Completing a perfect matching on the graph of the icosahedron.

The three antipodally symmetric perfect matchings containing the back and front edges.

The first type is called *cubic*.

Another view of an axial matching:

The edges of a cubic matching are disjoint from the edges of the axial matching with axis joining antipodal faces of the corresponding cube.

3. Counting Partitions

We count the number of possible partition labels:

5×3 arrays of pairs from $\{0, \dots, 5\}$ such that

1. each digit $\{0, \dots, 5\}$ occurs exactly once in each row;
2. each pair ij occurs exactly once in the array.

$$\begin{array}{ccc} 01|2i|jk & 01|2i|jk & 01|2i|jk \\ 02|1j|ik & 02|1j|ik & 02|1j|ik \\ 0i|??|?? & 0i|??|?? & 0i|1i|2k \\ 0j|??|?? & 0j|??|?? & 0j|1k|2j \\ 0k|??|?? & 0k|12|ij & 0k|12|ij \end{array}$$

There are six ways to form the rows with 01 and 02.

Each can be uniquely completed to a legal label.

THEOREM: There are exactly 6 edge partitions into antipodally symmetric perfect matchings.

4. Permuting the labels

Every permutation

$$\{0, 1, 2, 3, 4, 5\} \longrightarrow \{0, 1, 2, 3, 4, 5\}$$

induces a permutation

$$\{\text{partitions}\} \longrightarrow \{\text{partitions}\}$$

So we have a homomorphism

$$S_6 \rightarrow S_{\{\text{partitions}\}}$$

PROPOSITION: The homomorphism $S_6 \rightarrow S_{\{\text{partitions}\}}$ is an isomorphism

PROPOSITION: The homomorphism $S_6 \rightarrow S_{\{\text{partitions}\}}$ is an isomorphism

PROOF: The kernel is S_6 , A_6 or $\{1\}$.

So, if the kernel is non-trivial, every even permutation induces the identity on partitions.

Let's check (1 2 3):

5. Automorphisms of S_6

We have an isomorphism: $S_6 \rightarrow S_{\{\text{partitions}\}}$

If we assign numbers to the partitions, we have an automorphism: $h : S_6 \rightarrow S_6$

And: $h(1\ 2\ 3) = (0\ 3\ 4)(1\ 2\ 5)$

Conclusion: h is not inner.

How rare is that?

THEOREM: If $n \neq 6$, every automorphism of S_n is inner.

PROOF:

conjugation preserves the cycle structure of the permutations:

$$a_1 \xrightarrow{\sigma} a_2 \xrightarrow{\sigma} \dots \xrightarrow{\sigma} a_n \xrightarrow{\sigma} a_1,$$

a cycle of σ implies

$$\tau(a_1) \xrightarrow{\tau\sigma\tau^{-1}} \tau(a_2) \xrightarrow{\tau\sigma\tau^{-1}} \dots \xrightarrow{\tau\sigma\tau^{-1}} \tau(a_n) \xrightarrow{\tau\sigma\tau^{-1}} \tau(a_1),$$

is a cycle of $\tau\sigma\tau^{-1}$.

THEOREM: If $n \neq 6$, every automorphism of S_n is inner.

PROOF: (continued)

$$f \in \text{Aut}(S_n)$$

f maps the conjugacy class of transpositions to a conjugacy class of involutions.

f maps transpositions to the set of k disjoint transpositions, k fixed.

Transpositions: $\binom{n}{2}$

k disjoint transpositions: $\binom{n}{2k}(2k-1)(2k-3)\cdots(1)$

$\binom{n}{2} < \binom{n}{2k} \leq \binom{n}{2k}(2k-1)(2k-3)\cdots(1)$ if $2 < 2k < n-2$.

THEOREM: If $n \neq 6$, every automorphism of S_n is inner.

PROOF: (continued)

Cases: $2k - 2 = n$: $(2k - 1)(2k - 3) \cdots 1 = 1$, and so $k = 1$ and $n = 4$.

$2k - 1 = n$: $n = 2k + 1$

$$\binom{2k+1}{2} = \binom{2k+1}{2k} (2k-1)(2k-3) \cdots 1$$

$k = (2k - 1) \cdots (1)$ so $k = 1$, with $n = 3$.

$2k = n$:

$$\binom{2k}{2} = \binom{2k}{2k} (2k-1)(2k-3) \cdots 1$$

so $k(2k - 1) = (2k - 1)(2k - 3) \cdots 1$, or $k = (2k - 3) \cdots 1$, and $k = 3$ and $n = 6$.

CONCLUSION: If $n \neq 6$, then f must map transpositions to transpositions.

THEOREM: If $n \neq 6$, every automorphism of S_n is inner.

PROOF: (continued)

If $n \neq 6$, then f must map transpositions to transpositions.

Let h be an inner automorphism such that $h((0 k)) = f((0 k))$.

So $h^{-1}f(0 k) = (0 k)$ for all k .

$\{(0 k)\}$ generates S_n .

$h^{-1}f$ is the identity

$h = f$.
