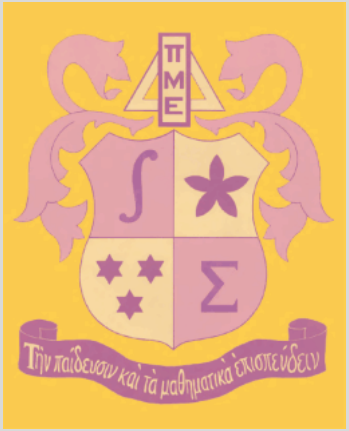
Combinatorial Rigidity and the Molecular Conjecture

Brigitte Servatius
Worcester Polytechnic Institute



The Proof of the Product Rule
To derivate a product as defined
The diff'rence quotient limit do compute,
And in that simple limit try to find
Each factor's diff'rence quotient, how astute!

But products of the functions at each x
Do not combine or factor, not on cue –
And fudging it does not survive the checks! :-(
A bit of clever insight finds the clue,

A product term with x's, ah, distinct
With plus and minus versions introduced.
The limit now with algebra succinct
Computes, so thus that rule can be deduced: :-)

Add factor one times factor two derived
To factor two times factor one derived.

1. Introduction

Generic rigidity in the plane is a graph theoretic property:

Theorem 1 *(Laman - 1970)[7] A graph is generically rigid in the plane if and only if it has a subset $|E|$ of edges with*

$$|E| = 2|V(E)| - 3$$

and, for every subset $F \subseteq E$,

$$|F| \leq 2|V(F)| - 3.$$

2. Type of Rigidity

We will use the term *framework* (in m-space) to denote a triple $(V, E, \overrightarrow{p})$, where (V, E) is a graph and $\overrightarrow{p}$ is an embedding (injection) of V into real m-space.

We say that a framework is *globally rigid* (in m-space) if all solutions to the system of quadratic equations obtained from requiring all edge lengths to be fixed, with the coordinates of the vertices as variables, correspond to congruent frameworks; we say that a framework is *rigid* (in m-space) if all solutions to the corresponding system in some neighborhood of the original solution (as a point in mn-space) come from congruent frameworks.

We say that a given framework $(V, E, \overrightarrow{p})$ is *generic* if all frameworks corresponding to points in a neighborhood of $P = \overrightarrow{p}(V)$ in $\mathbb{R}^{nm}$ are rigid or not rigid as is $(V, E, \overrightarrow{p})$. A set of points P in m-space is said to be *generic* if each framework $(V, E, \overrightarrow{p})$ with $\overrightarrow{p}(V) = P$ is generic.

If $G(V, E)$ is not rigid, we call the maximal rigid subgraphs of G the *rigid components* and note that rigid components partition E. Then $\mathcal{M}(G)$ is the direct sum over its restrictions on the rigid components.

The following theorem is equivalent to Laman's Theorem 1, it uses the rank function of $\mathcal{M}$ rather than independence to characterize rigidity.

$G(V, E)$ is called *redundantly rigid* if $G(V, E - e)$ is rigid for all $e \in E$, i.e. the removal of a single edge e from the rigid graph G does not destroy rigidity. Redundant rigidity is a key to characterize global rigidity.

Theorem 3 *[5] Let G be a graph. Then G is globally rigid if and only if G is a complete graph on at most three vertices, or G is both 3-connected and redundantly rigid.*

However,Lovász and Yemini [9] note that their proof technique will show that $G - \{e_1, e_2, e_3\}$ is rigid for all $e_1, e_2, e_3 \in E$, and hence that G is redundantly rigid. This result was combined with Theorem 3 in [5] to deduce

Theorem 6 *Every* 6*-connected graph is globally rigid.*

5. Random graphs

Let $G_{n,d}$ denote the probability space of all d-regular graphs on n vertices with the uniform probability distribution. A sequence of graph properties A_n holds asymptotically almost surely, or a.a.s. for short, in $G_{n,d}$ if $\lim_{n\to\infty} \Pr_{G_{n,d}}(A_n) = 1$. Graphs in $G_{n,d}$ are known to be a.a.s. highly connected. It was shown by Bollobás [1] and Wormald [12] that if $G \in G_{n,d}$ for any fixed $d \geq 3$, then G is a.a.s. d-connected. This result was extended to all $3 \leq d \leq n-4$ by Cooper et al. [3] and Krivelevich et al. [6]. Stronger results hold if we discount 'trivial' cutsets. In [13], Wormald shows that if $G \in G_{n,d}$ for any fixed $d \geq 3$, then G is a.a.s. cyclically $(3d-6)$-edge-connected.

Let $G(n,p)$ denote the probability space of all graphs on n vertices in which each edge is chosen independently with probability p. In the following we will assume that all logarithms are natural. We will need the following results on $G(n,p)$.

Lemma 1 *Let $G \in G(n,p)$, where $p = (\log n + k \log\log n + w(n))/n$, $k \geq 2$ is an integer and $\lim_{n\to\infty} w(n) = \infty$. For each fixed integer t, let S_t be the set of vertices of G of degree at most t. Then, a.a.s.*
(a) S_{k-1} is empty,
(b) no two vertices of S_t are joined by a path of length at most two in G,
(c) $G - S_{t-1}$ is non-empty and t-connected.

PROOF: Facts (a) and (b) are well known, see for example [2]. Fact (c) follows from (a), (b) and [10, Theorem 4] □

Open problems

Theorem 9 *Let $G \in G(n,p)$, where $p = (\log n + k \log\log n + w(n))/n$, and $\lim_{n\to\infty} w(n) = \infty$.*
(a) If $k = 2$ then G is a.a.s. rigid.
(b) If $k = 3$ then G is a.a.s. globally rigid.

PROOF: (a) We adopt the notation of Lemma 1. It follows from Lemma 1 that a.a.s. $S_1 = \emptyset$ and $G - S_5$ is a.a.s. 6-connected. Hence $G - S_5$ is a.a.s. (globally) rigid by Theorem 6. Since adding a new vertex joined by at least two new edges to a rigid graph preserves rigidity, it follows that G is a.a.s. rigid.
(b) This follows in similar way to (a), using the facts that $S_2 = \emptyset$ and that adding a new vertex joined by at least three new edges to a globally rigid graph preserves global rigidity. □

The bounds on p given in Theorem 9 are best possible since if $G \in G(n,p)$ and $p = (\log n + k \log\log n + c)/n$ for any constant c, then G does not a.a.s. have minimum degree at least k, see [2].

Let $Geom(n, r)$ denote the probability space of all graphs on n vertices in which the vertices are distributed uniformly at random in the unit square and each pair of vertices of distance at most r are joined by an edge. Suppose $G \in Geom(n, r)$. Li, Wan and Wang [8] have shown that if $n\pi r^2 = \log n + (2k - 3)\log\log n + w(n)$ for $k \geq 2$ a fixed integer and $\lim_{n\to\infty} w(n) = \infty$, then G is a.a.s. k-connected. As noted by Eren et al. [4], this result can be combined with Theorem 6 to deduce that if $n\pi r^2 = \log n + 9\log\log n + w(n)$ then G is a.a.s. globally rigid. On the other hand, it is also shown in [8] that if $n\pi r^2 = \log n + (k-1)\log\log n + c$ for any constant c, then G is not a.a.s. k-connected. It is still conceivable, however, that if $n\pi r^2 = \log n + \log\log n + w(n)$ then G is a.a.s. rigid, and that if $n\pi r^2 = \log n + 2\log\log n + w(n)$ then G is a.a.s. globally rigid.

8. Molecular Conjecture in the Plane

Given: Simple graph $G = (V, E)$.

- Regard G as a body and pin graph of a structure in the plane:

  Vertices are bodies.

  Edges denote pins.

- Note: Each pin connects just two bodies. Otherwise we would need a hyper-graph.

- Realizations:

  – Amorphous bodies. Embedding specifies the location of the pins.

  – Line bodies. Embedding may specify either lines or pins.

  – Question: Does the line realization always exist?

Recent Advances in the Generic Rigidity of Structures, Tiong-Seng Tay and Walter Whiteley Structural Topology # 9, 1984 Many body and hinge structures are built under additional constraints. For example in architecture flat panels may be used in which all hinges are coplanar. In molecular chemistry, we can model molecules by rigid atoms hinged along the bond lines so that all hinges to an atom are concurrent. This is the natural projective dual for the architectural condition.

Conjecture: A multigraph is generically rigid for hinged structures in n-space iff it is generically rigid for hinged structures in n-space with all hinges of body v_i in a hyperplane H_i of the space.

11. Open problems

- Is the solution of the molecular conjecture useful for computational biology?
- Translate combinatorial allostery to molecules.
- Are random 6-regular graphs rigid in 3-space?
- Generalizations to tensegrities?
- Can sparse random graphs be realized as unit distance graphs?
