#Tags	#Diabetes, #Type 1 Diabetes
Summary of key points + notes (include methodology)	Type 1 diabetes is an autoimmune disease where unidentified triggers cause autoantibodies to destroy insulin producing beta cells of the pancreas. Autoantibodies are produced before the onset of the disease and have been identified, allowing type 1 diabetes to be predicted through screening for these autoantibodies. Screening along with other specific researched therapies besides insulin therapy allow for type 1 diabetes to be delayed, treated earlier, or have its progression prevented.
Research Question/Problem/Need	How can type 1 diabetic care and treatment be improved with screening for warning signs before the disease onsets?

Source type	Journal Article
Keywords	Diabetes, Hyperglycemia, Oxidative stress, Insulin resistance, Telomere
#Tags	#Diabetes, #Type 1 Diabetes, #Type 2 Diabetes, #Telomere
Summary of key points + notes (include methodology)	This paper gave the summary of multiple relations or connections found between telomere lengths and diabetes or diabetes related issues. The overall conclusion to be derived from the multiple referenced studies is that type 1 and 2 diabetes' pathogenesis and complications are associated with shorter telomeres in cells. This is likely because of both type 1 and 2 diabetes having higher levels of oxidative stress, which is also tied to shorter telomeres.
Research Question/Problem / Need	What is the relationship between telomere lengths and diabetes?

VOCAB: (w/definition)

Non-communicable: not capable of being passed from one person to another, specifically referring to conditions like non-communicable diseases (NCDs) which are not transmitted through direct contact or other means of infection (chronic, autoimmune diseases, or cancer)

Leukocyte: white blood cell

Mechanistic: relating to theories which explain phenomena in purely physical or deterministic terms

Comorbidity: the simultaneous presence of two or more diseases or medical conditions in a patient

Oxidative Stress: a state of imbalance between the production of reactive oxygen species (ROS) and the body's ability to counteract their harmful effects with antioxidants

Inflammation: a complex biological response that occurs when the body detects an injury, infection, or other harmful stimulus. It is a protective mechanism designed to eliminate the threat and promote healing. Common symptoms of inflammation include redness, swelling, heat, or pain in the affected area

Follow up Questions	Have studies been conducted to research the effects of any telomerase treatment therapies on diabetes, its progression, or its complications?

Article #3 Notes: Ozempic-style drugs treat type 1 diabetes, not only type 2, study finds

Source Title	Ozempic-style drugs treat type 1 diabetes, not only type 2, study finds
Source citation (APA Format)	Zieba, J. (2025, July 3). Ozempic-style drugs treat type 1 diabetes, not only type 2, study finds. Live Science. https://www.livescience.com/health/medicine-drugs/ozempic-style-drugs-treat-type-1-diabetes-not-only-type-2-study-finds
Original URL	https://www.livescience.com/health/medicine-drugs/ozempic-style-drugs-treat-type-1-diabetes-not-only-type-2-study-finds
Source type	Website
Keywords	Diabetes, Type 1 Diabetes, Type 2 Diabetes, Semaglutide
#Tags	#Diabetes, #Type 1 Diabetes, #Type 2 Diabetes, #Ozempic
Summary of key points + notes (include methodology)	<p>Semaglutide is the main ingredient of type 2 diabetic drug treatments like Ozempic. Semaglutide helps to control blood sugar levels in type 2 diabetics by reducing a liver-made hormone that raises blood sugar, which also slows down digestion, making recipients feel fuller for longer and giving the pancreas more time to release the proper amount of insulin for the digesting food. To collect data on the effectiveness of semaglutide treatment in type 1 diabetics, the researchers had 72 type 1 diabetics who also had obesity. 36 received a weekly semaglutide injection along with their traditional insulin replacement treatment, while the other 36 participants had a placebo in place of the semaglutide. This spanned for 26 weeks and all the participant's blood sugar were monitored with continuous glucose monitors. Results showed that the patients receiving semaglutide had overall better control of their blood sugar. They were able to stay in acceptable ranges of their BG for over 70% of the recorded time period in addition with spending less time on low BG levels. Those receiving semaglutide also lost a minimum of 5% of their body weight, while no one in the placebo group was able to experience all three of these benefits.</p>

Research Question/Problem/Need	Does the application of semaglutide act benefit type 1 diabetics in blood sugar management?
Important Figures	No graphical figures provided
VOCAB: (w/definition)	
Cited references to follow up on	Nature Medicine Journal Article on similar premise: https://www.nature.com/articles/s41591-024-03463-z
Follow up Questions	<p>Although recipients were able to experience better BG levels, would the same results be able to be achieved through better type 1 diabetes management?</p> <p>For implications, what distinction would need to be made among type 1 diabetics to receive this sort of treatment (BMI level, consistent difficulty with BG levels, etc.)?</p>

Article #4 Notes: A new diabetes treatment could free people from insulin injections

Source Title	A new diabetes treatment could free people from insulin injections
Source citation (APA Format)	Rosen, M. (2025, July 2). A new diabetes treatment could free people from insulin injections. Science News. https://www.sciencenews.org/article/type-1-diabetes-cell-therapy-insulin
Original URL	https://www.sciencenews.org/article/type-1-diabetes-cell-therapy-insulin
Source type	Website
Keywords	Diabetes, Type 1 Diabetes, Insulin, Vertex Pharmaceuticals
#Tags	#Diabetes, #Type 1 Diabetes, #Insulin Replacement Therapy
Summary of key points + notes (include methodology)	<p>The FDA approved a pancreatic cell replacement therapy in 2023 where the pancreatic cells of deceased donors are infused into the bodies of type 1 diabetics to replace their destroyed pancreas cells. Despite this, the availability and quality of these cells are in low numbers. Because of this, the researchers in this article ran a small trial of 14 type 1 diabetics where doctors infused lab-made islet cells into the veins of patients. Upon infusion, the cells were able to act immediately in producing insulin and 10 out of the 12 participants no longer needed insulin replacement therapy even a year after treatment. The other two participants reduced their insulin doses by up to 70%. An array of side effects struck the participants, including diarrhea, headaches, nausea, and infection of COVID-19 which were caused by immunosuppressive drugs that patients had to consistently take to prevent the body from destroying the infused islet cells. Two unrelated deaths were also caused, one from a surgery complication and the other from a preexisting brain injury. This study has been expanded to 50 participants and the data collected from these patients are hoped to have been applied for approval as a therapy in 2026.</p>

Research Question/Problem/ Need	Can infused lab-grown pancreas islet cells be used to replace destroyed type 1 diabetic's beta cells?
Important Figures	No figures shown in the ScienceNews article
VOCAB: (w/definition)	
Cited references to follow up on	Research article of experiment: https://www.nejm.org/doi/full/10.1056/NEJMoa2506549?query=featured_home
Follow up Questions	<p>Are the lab-grown islet cells cultivated or engineered in any unique way to be able to replace destroyed beta cells and to survive better in a foreign internal environment?</p> <p>What factors contributed to the two unrelated deaths in the initial trial outlined in this study? What surgical complications could have caused a death in a recipient and what role did the other recipient's brain injury have to play in the outcome of their treatment?</p> <p>Are there possible alternatives to immunosuppressants or are the lab-grown islet cells able to be engineered in a way to bypass the recipient's body's defenses?</p>

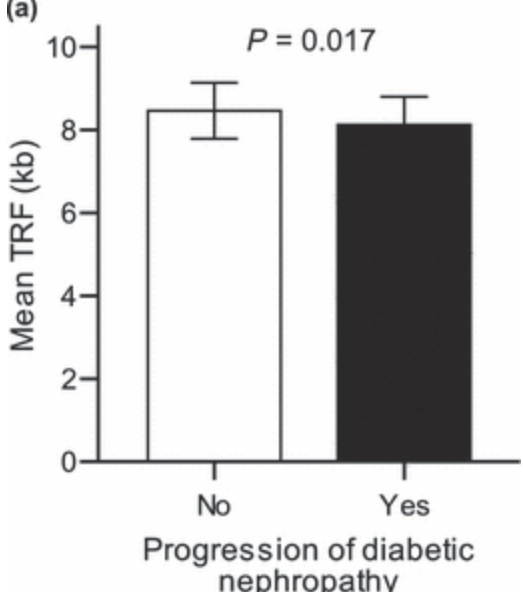

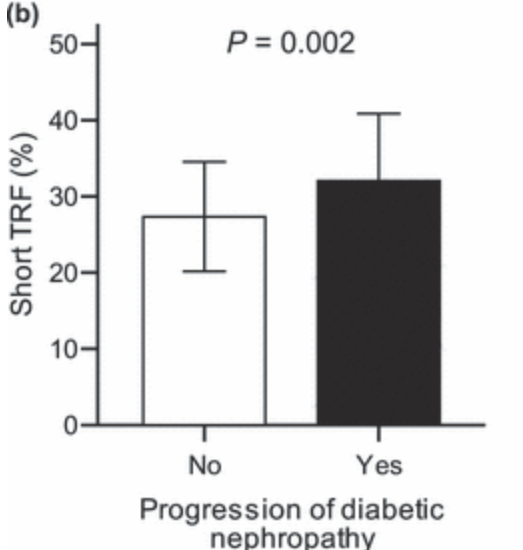

Article #5 Notes: Should doctors screen all kids for type 1 diabetes?

Source Title	Should doctors screen all kids for type 1 diabetes?
Source citation (APA Format)	Couzin-Frankel, J. (2024, March 13). Should doctors screen all kids for type 1 diabetes? Science AAAS. https://www.science.org/content/article/should-doctors-screen-all-kids-type-1-diabetes
Original URL	https://www.science.org/content/article/should-doctors-screen-all-kids-type-1-diabetes
Source type	Website
Keywords	Diabetes, Type 1 Diabetes, Screening
#Tags	#Diabetes, #Type 1 Diabetes, #Type 1 Diabetes Screening
Summary of key points + notes (include methodology)	<p>Blood tests have been a known method to predict the onset of type 1 diabetes. Studies have been released show that these preemptive screenings decrease or prevent the effects of life threatening complications associated with disease onset. These screenings look for signs including high blood sugar and autoantibodies in the blood that are known for attacking insulin-producing cells in the pancreas. Screening in this way, especially for the autoantibodies is crucial and a very good indicator. This is because almost 45% of children with at least two types of these autoantibodies will develop T1D in the next 5 years and are almost guaranteed to develop it within their lifetime. In areas that screen in this way, rates of diabetic ketoacidosis, a common life-threatening condition caused by the onset, drop to less than 10% of their usual rates. The drug teplizumab is also shown to be able to delay onsets by 2 to 3 years. This drug is delivered into the blood stream of those who have been determined at risk for the disease for 2 weeks in order to achieve this effect and the drug is under review by European drug authorities at the time of the article's writing (March of 2024).</p>
Research Question/Problem/Need	Should T1D screening efforts be expanded?
Important Figures	No figures were shown in the AAAS article

VOCAB: (w/definition)	Intravenously: into or within a vein
Cited references to follow up on	Teplizumab treatment for T1D: https://www.nejm.org/doi/full/10.1056/NEJMoa2308743
Follow up Questions	Won't patients have to be repeatedly screened for abnormal BG levels and autoantibodies or is the presence of autoantibodies there since birth or a very young age?

Article #6 Notes: Telomere length and progression of diabetic nephropathy in patients with type 1 diabetes

Source Title	Telomere length and progression of diabetic nephropathy in patients with type 1 diabetes
Source citation (APA Format)	Fyhrquist, F., Tiitu, A., Saijonmaa, O., Forsblom, C., & Groop, P. H. (2010, February 1). Telomere length and progression of diabetic nephropathy in patients. <i>Journal of Internal Medicine</i> , 267(3), 278-286. http://onlinelibrary.wiley.com/doi/10.1111/j.1365-2796.2009.02139.x/full
Original URL	https://onlinelibrary.wiley.com/doi/full/10.1111/j.1365-2796.2009.02139.x
Source type	Journal article
Keywords	Diabetic nephropathy, microalbuminuria, telomeres, type 1 diabetes
#Tags	#Diabetes, #Type 1 Diabetes, #Diabetic Nephropathy, #Telomeres
Summary of key points + notes (include methodology)	<p>The researchers conducted a baseline clinical investigation that took 132 type 1 diabetic patient's urinary albumin excretion rate (AER) to determine their initial progression of nephropathy. Blood samples were also taken to analyze the patient's telomere length and other variables that could be compared in analysis to the telomere length like A1c (average blood glucose level over a 2-3 month period).</p> <p>Follow up measurements of these values were taken an average of 6.9 years later to examine the progression of nephropathy and its relation to reduction of telomere length and other factors.</p> <p>Of the 21 patients that progressed in nephropathy, progressors had a shorter average telomere length and a higher % of short telomeres (telomeres <6.6kilobases in length) showing that telomere length and % of short telomeres were both predictors of nephropathy.</p>
Research Question/Problem/Need	Are shorter telomere lengths in type 1 diabetics associated with or predictive of progression of the disease?

<p>Important Figures</p>	<p>(a)</p>  <p>Mean TRF (kb)</p> <p>$P = 0.017$</p> <p>No Yes</p> <p>Progression of diabetic nephropathy</p> <p>(b)</p>  <p>Short TRF (%)</p> <p>$P = 0.002$</p> <p>No Yes</p> <p>Progression of diabetic nephropathy</p>
<p>VOCAB: (w/definition)</p>	<p>Leucocytes: (plural form of leukocyte) white blood cells</p> <p>Nephropathy: kidney/renal disease</p> <p>Urinary albumin: albumin (a type of blood protein) found in urine. Original URL	https://diabetesjournals.org/diabetes/article/68/5/988/39756/HLA-Class-II-Antigen-Processing-and-Presentation
Source type	Journal Article
Keywords	
#Tags	#Diabetes, #Type 1 Diabetes, #HLA II, #Beta Cell
Summary of key points + notes (include methodology)	In type 1 diabetes, T-cell subsets CD8+ and CD4+ and B cells infiltrate pancreatic islets and target beta cells by recognizing type 1 diabetes autoantigens. Antigen presentation to T cells is mediated by APCs (antigen-presenting cells) through HLA Class I (found in most cells with a nucleus) and Class II molecules (specialized immune cells). Past immunohistochemical studies of donor pancreas samples consistently show larger amounts of Class I molecules in islets from type 1 diabetics as compared to nondiabetics. Multiple studies have also shown that beta cells from type 1 diabetics have expressed Class II molecules. This expression of Class II molecules was written off because there are no Class II molecules expressed in persons without T1D. The implications of Class II molecules being expressed in pancreatic beta cells have been debated and were unclear.

Researchers obtained donated pancreatic islet tissue from various nondiabetic and type 1 diabetic biobanks or donation groups. T1D islets were dissociated, fixed, and stained according to the procedures in the referenced journal article by [Blodgett et al.](#) T1D human islets were isolated, RNA sequenced, and immunostained for intracellular insulin and glucagon. The cells displaying insulin and glucagon were RNA sequenced to create a RNA sequence library. Comparing the libraries of diabetic and non-diabetic patients, the researchers found 650 differentially expressed genes in beta cells of type 1 diabetics, with proinflammatory-associated genes, and Class I and II pathway genes being found to be upregulated in diabetic beta cells. Class II transactivator expression was coexpressed alongside Class II genes in diabetic cells.

Research Question/Problem/Need
 What is the significance of Class II HLA molecules being expressed in type 1 diabetic pancreatic beta cells?

VOCAB: (w/definition)

Immunohistology: microscopic study of tissues using antibodies to bind to antigens

Immunohistochemical: lab technique used to identify and visualize antigens in a tissue sample

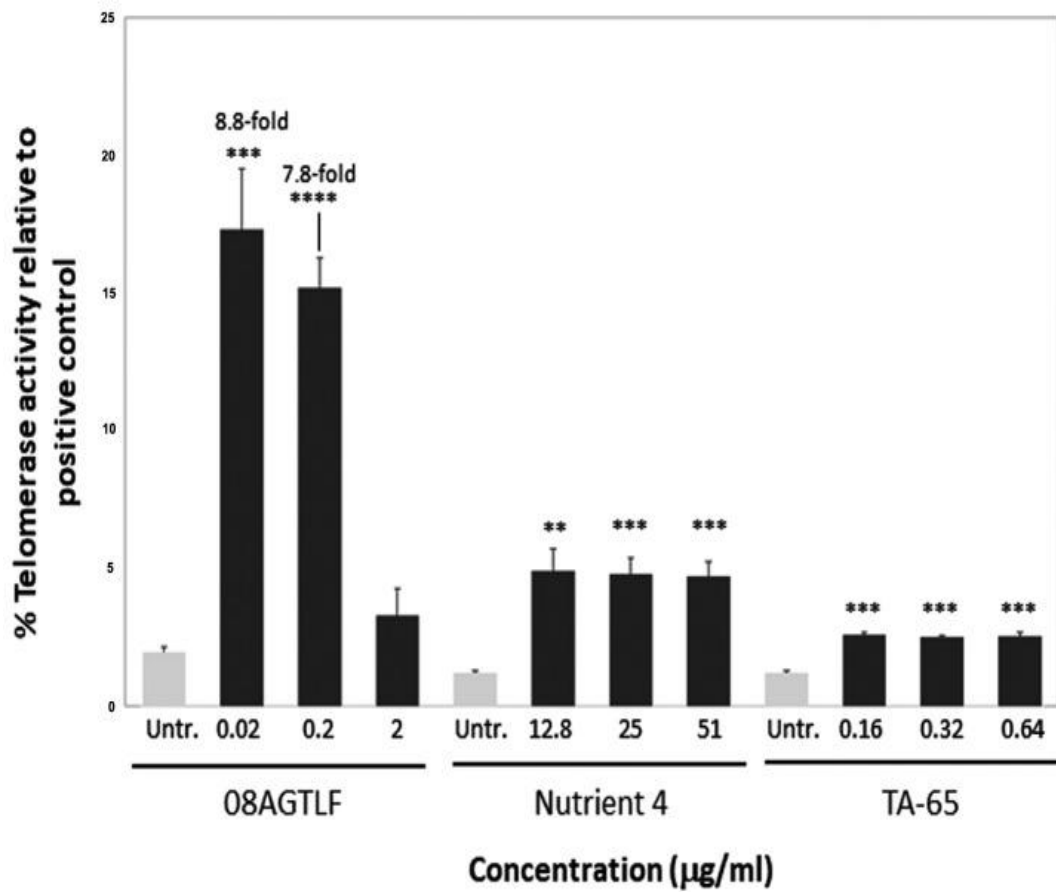

Antigen: molecule that the immune system recognizes as foreign and that triggers an autoimmune response

	<p>Human Leukocyte Antigen (HLA) molecules: a protein on the surface of cells that presents antigens to T cells, helping the immune system distinguish “self” from “non-self”</p> <p>Antigen-Presenting Cells (APCs): immune cells that present antigens to T cells to initiate a specific immune response</p> <p>Nucleated cells: cells that have a nucleus</p> <p>Dendritic cells: immune cells that capture and present antigens to T cells</p> <p>Macrophages: immune cells that combat antigens and promote tissue repair</p> <p>Aberrant: (Biology) diverging from the normal type</p> <p>Equivocal: open to interpretation; ambiguous</p> <p>Phagocytize: phagocytic cells (type of immune cell that engulfs and destroys foreign particles) ingesting bacteria or other material</p> <p>Permeabilize: to make permeable</p> <p>Upregulated genes: when a cell increases the production of proteins, often as a response to a signal for cellular function</p> <p>Downregulated genes: vice versa process of upregulated genes as a response to a signal for cellular function</p> <p>Intracellular: something located inside or within a cell</p> <p>Upstream: on DNA strands, closer to the 5 prime end</p> <p>Downstream: on DNA strands, closer to the 3 prime end</p> <p>Endocrine: network of glands that produce hormones to regulate bodily functions</p>
<p>Cited references to follow up on</p>	
<p>Follow up Questions</p>	<p>Have there been further studies that have synthesized these findings to support developments in treating the disease?</p>

Article #8 Notes: Discovery of potent telomerase activators: Unfolding new therapeutic and anti-aging perspectives

Source Title	Discovery of potent telomerase activators: Unfolding new therapeutic and anti-aging perspectives

Keywords	Telomere, telomerase, senescence, diabetes mellitus, glucose intolerance, insulin secretion, beta-cell
#Tags	#Telomerase, #Beta Cell
Summary of key points + notes (include methodology)	Evidence suggests that telomeres and telomerase activity have a crucial role in regulating cell survival/regeneration. Mice that were genetically deficient for the telomerase RNA component (<i>Terc</i>) gene—labelled G4-ko-- were analyzed and found that their body masses were smaller, yet body compositions and metabolism remained proportionally the same relative to their size. Concentrations of various metabolic plasma markers like glucose, insulin, fatty acids, triglycerides, and so on were also measured from blood samples of control and experimental mice genotypes where no differences were found. Intra-peritoneal glucose tolerance tests (ipGTT) and intra-peritoneal insulin tolerance tests (ipITT) were performed on the mice to find that the G4-ko mice had increased levels of insulin tolerance and impaired glucose clearing. Impaired insulin secretion was observed in response to injected glucose from ipGTT tests as well. Telomere lengths were measured to find that G4-ko mice had shorter telomeres on average using quantitative fluorescence in situ hybridization (qFISH). This shows that deficient telomerase causes shorter telomere lengths in pancreatic islets, impaired glucose tolerance, and impaired insulin secretion in the mice. Pancreatic beta cell islet masses were also found to be reduced through quantitative microscopy where the smaller size of the G4-ko mice was accounted for.

<p>Research Question/Problem/Need</p>	<p>Does telomerase activity act as a key regulator for pancreatic beta cell viability and regeneration?</p>

Article #10 Notes: Telomere length predicts all-cause mortality in patients with type 1 diabetes

Source Title	Telomere length predicts all-cause mortality in patients with type 1 diabetes
Source citation (APA Format)	Astrup, A. S., Tarnow, L., Jorsal, A., Lajer, M., Nzietchueng, R., Benetos, A., Rossing, P., & Parving, H.-H. (2010). Telomere length predicts all-cause mortality in patients with type 1 diabetes. <i>Diabetologia</i> , 53(1), 45–48. https://doi.org/10.1007/s00125-009-1542-1
Original URL	https://doi.org/10.1007/s00125-009-1542-1
Source type	Journal Article
Keywords	Diabetic nephropathy, mortality, telomere length, type 1 diabetes
#Tags	#Telomeres
Summary of key points + notes (include methodology)	In 1993, 198 voluntary patients with type 1 diabetes had their urinary albumin levels and telomere lengths measured to determine their development of diabetic nephropathy and overall telomere length. Patients were followed until September 1 st , 2006 or until they died. 192 type 1 diabetics with consistent normoalbuminuria were used as a control. Telomere lengths were not found to be different in patients with or without diabetic nephropathy and were not related to end-stage renal disease. It was found that all-cause mortality rates were higher in tertiles with shorter telomere lengths.
Research Question/Problem/Need	Can the length of telomeres be used as an identifier to point out type 1 diabetics who have diabetic nephropathy being at a high risk of death?

<p>Important Figures</p>	<p>The figure is a Kaplan-Meier survival plot. The vertical axis is labeled 'Cumulative mortality (%)' and ranges from 0 to 25 in increments of 5. The horizontal axis is labeled 'Follow-up time (years)' and ranges from 0 to 12.5 in increments of 2.5. There are three curves representing different groups. The solid line (top) shows the highest cumulative mortality, reaching approximately 23% at 12.5 years. The dotted line (middle) reaches approximately 20% at 12.5 years. The dashed line (bottom) shows the lowest cumulative mortality, reaching approximately 12% at 12.5 years. All curves start at 0% at time 0 and show a step-wise increase over time.</p>
<p>VOCAB: (w/definition)</p>	<p>Prognostic: serving to predict the likely outcome of a disease or ailment</p> <p>All-cause mortality: overall death rate from all possible causes within a specific population over a defined period of time</p> <p>Tertile: one of three groups in which a set of data is divided</p>
<p>Cited references to follow up on</p>	
<p>Follow up Questions</p>	<p>Would it be proper to link shorter telomere lengths as the only factor to higher likelihoods of all-cause death? This feels misleading as shorter telomeres are caused by repeated cell division and one of the causes of aging and age related diseases. If shorter telomeres are an indicator of higher rates of mortality, wouldn't it make sense for the authors to label age as an indicator of this as well?</p>

Article #11 Notes: A Brief Introduction to Design of Experiments

Keywords	Design of experiments, statistical analyses, multivariable
#Tags	#DoE
Summary of key points + notes (include methodology)	Design of experiments or experimental design is a method of conducting and analyzing tests that is able to analyze the independent influence of a factor in a multivariable test. This method minimizes the amount of runs or data that needs to be gathered, while increasing the amount of information collected. The core principles in experimental design are randomization (to protect against bias), replication (to increase the sample size and precision), blocking (increasing precision by removing the effect of known nuisance factors: e.g. performing a baseline and experimental procedure on samples of material <u>from the same batch</u>), orthogonality (making the effects of factors independent of one another), and factorial experimentation (method that estimates the effects of each factor and combinations of factors). This process is mainly used to discover interactions among factors, screening for many factors, optimizing a process, establishing/maintaining quality control, or designing robust products.
Research Question/Problem/Need	What is design of experiments, its use cases, and overall function process?

Keywords	Bioreactor, CFD, cultivated meat production

<p>#Tags</p>	<p>#Bioreactor, #CFD</p>																																																								
<p>Summary of key points + notes (include methodology)</p>	<p>Review of CFD modelling in stirred tank bioreactors: Stirred tank bioreactors are the most widely used type of bioreactors for cell multiplication. Multiple CFD studies have found impactful findings in these types of bioreactors. One study for example established that the scale of a bioreactor is very impactful. The study showed that the impeller speed that works in a smaller 125ml bioreactor does not result in the same suspension criterion (~99% microcarrier suspension) as a 500ml bioreactor. More impeller blades have also been shown to not always translate to better mixing or higher shear, showing that geometry matters and needs to be tested for. CFD simulation has also shown promise in designing larger scale stirred tank bioreactors in ranges upwards of thousands of liters of volume. Limitations are present in modeling these types of bioreactors with CFD however. The main being that behavior of many factors and criteria do not uniformly increase or change with scale, meaning that modeling scaled up models requires retesting, not extrapolation of already tested models.</p>																																																								
<p>Research Question/Problem/Need</p>	<p>Meat demand is growing and lab-grown meat is a plausible option to addressing this issue. Bioreactors are means of producing lab-grown meat, yet need to be upscaled and specialized to the meat cells.</p>

Article #13 Notes: Economic drivers and trade-offs in antibody purification processes

Source Title	Economic drivers and trade-offs in antibody purification processes
Source citation (APA Format)	<i>Economic Drivers and Trade-Offs in Antibody Purification Processes</i> BioPharm International. (2025, November 30). https://www.biopharminternational.com/view/economic-drivers-and-trade-offs-antibody-purification-processes-0
Original URL	https://www.biopharminternational.com/view/economic-drivers-and-trade-offs-antibody-purification-processes-0
Source type	Journal article
Keywords	Monoclonal antibody, upstream production, downstream production
#Tags	#Product Economics
Summary of key points + notes (include methodology)	With the demand and production of monoclonal antibodies increasing, the costs of upstream processing have decreased, yet the inverse has occurred for downstream processes. As shown by Sommerfeld and Strube, increasing fermentation titer from 0.1 to 1g/L changed the ratio of USP to DSP costs from 55:45 to 30:70, showing that USP costs are inversely correlated to titer. Indirect costs, such as overhead costs, and labor costs proportionally decrease in USP as scale increases, with the only thing that increases in cost is the use of raw materials. In downstream processing, however, costs only increase as scales are increased. To address these increased downstream costs, the industry is increasing downstream processing yields, eliminating intermediate steps such as ones that include buffer exchange, and reducing the duration of batches. This is done by taking advantage of improvements in chromatography resins that allow increased throughput over shorter times; and lower buffer demands and validation costs using new technologies such as membrane chromatography
Research Question/Problem/Need	With the increasing demand and production of monoclonal antibodies, process changes are needed to address the increasing downstream processing costs that result from this larger scale production.

Important Figures

Table 1. Example of downstream process economic trade-offs

Membrane chromatography versus packed-bed chromatography	
Advantages	Investment ↓ Buffer cost ↓ Labor cost ↓ Cleaning validation cost ↓ Development cost ↓
Disadvantages	Separation medium cost ↑

VOCAB: (w/definition)

Upstream process: focuses on the initial stages like resource extraction or cell cultivation

Downstream process: downstream focuses on the later stages of refining, purification, and delivery to the customer

Titer: the concentration of an antibody

Keywords	Process development; manufacturing costs; biopharmaceutical; drug development cycle; chemistry, manufacturing and controls; clinical success rates; phase transition rates
#Tags	#Product Economics
Summary of key points + notes (include methodology)	A case study was set up to estimate the chemistry, manufacturing, and controls activity budgets for process development and manufacturing at each phase of product development. This case study uses a process-economics model focused on mammalian cell culture systems to estimate costs, while making multiple assumptions and computations to establish, material demand and development path and scale. The study found that under an average case scenario, where approval success rate is 12%, one market success/year is estimated to cost \$780 million, with the value of the dollar being based on 2020's inflation values. Process development and manufacturing costs have been calculated to contribute 13-17% of this amount. Regulatory review or commercial preparation stages contribute the most to this total cost of about 31%. Phase III costs contribute 24%, preclinical and Phase I 20% each, and phase II about 5%. In a worst case scenario with phase approval success rates at 4%, estimated costs increase by an estimated 2.5 times compared to the average case scenario.

Research Question/Problem/Need
 Published studies have studied the decreasing phase approval success rates dropping and increasing research and development costs for new biopharmaceuticals, yet have not addressed the cost breakdowns through clinical, process development, and manufacturing activities at each phase. Based on various sources, Table 1 was constructed outlining the best, average, and worst case scenarios when it comes to phase approval rates of projects.

Source type	Journal article
Keywords	Monoclonal antibodies, pharmaceuticals, downstream, upstream, CHO cells,
#Tags	#Product Economics
Summary of key points + notes (include methodology)	Three different models were made for three different production methods. At the industrial scale, the model was centered around stable gene expression in CHO, while at a smaller scope was transient gene expression in CHO cells. These were in comparison to cell-free protein synthesis which used CHO cell lysates. Each process was simulated with SuperPro Designer which considered the upstream/downstream processes, and factors like overall costs of production (operating costs, investment, product yield). With this, the conclusions of the study show that the novel system is not cost-competitive with traditional methods because of higher costs for materials at normal scales. At smaller scales, however, the novel design process shows economic promise at smaller scales like small-batch or on-demand production. This is because in those cases, flexibility and speed of production matter more than overall scale or yield. In order for the cell-free protein synthesis system to be improved, the method needs to produce higher yields of mAbs and to implement cost reduction or recycling strategies for expensive components like plasmid DNA.
Research Question/Problem/Need	Can a cell-free protein synthesis system with CHO cell extracts be economically competitive to traditional manufacturing of mAbs

#Tags	#Bioreactor, #Product Economics																																																				
Summary of key points + notes (include methodology)	Existing cost studies for monoclonal antibody facilities were reviewed in order to amount information about the economics surrounding large-scale mAb production, specifically breaking it into upstream and downstream processes. Main conclusions included that chromatography processes make up the majority of downstream costs because resins are comparatively expensive. In the upstream processes, larger scale production reduces the production cost/gram of antibodies, yet influences downstream costs because more product needs to be purified.																																																				
Research Question/Problem/Need	What are the specific operating costs and relationships between downstream and upstream mAbs production?

Source type	Journal article
Keywords	Bioreactor control systems · Digitization · Advanced process control · Industrial automation · Single-use technology · Biopharmaceuticals
#Tags	#Bioreactor, #Product Economics
Summary of key points + notes (include methodology)	<p>Despite traditional control systems (like PID controllers and simpler setups) making up over 90% of today's industrial bioprocess controls, these methods are often insufficient for the increasing complexity, nonlinearity, and regulatory demands of modern biotech processes. The authors describe a variety of control strategies — from basic device-level control to distributed control systems (DCS), programmable logic controllers (PLCs), supervisory control (SCADA), and advanced modeling-based control — and discuss their pros and cons depending on reactor configuration, scale, and product type. They highlight recent trends: adoption of “single-use” bioreactors (for flexibility and sterility), improved sensor technologies, real-time monitoring, and more sophisticated process modelling. These advances are becoming necessary as bioprocesses grow more complex and require stricter quality control. The paper argues that future biopharmaceutical manufacturing will increasingly depend on advanced control and automation — combining good sensor data, flexible/reactive control systems, and computational modeling — to achieve efficiency, scalability, and consistent product quality</p>
Research Question/Problem/Need	Review article discussing the industrial aspects and control strategies for operating bioreactors to provide future prospects of industrial development and potential new strategies for process control in the biopharmaceutical industry.

Source type	Bioprocess International Magazine Article
Keywords	Bioreactor, Scale-up, Fluid flow, shear stress, temperature distribution, geometry
#Tags	#Bioreactor
Summary of key points + notes (include methodology)	<p>Scaling up bioreactor processes can be difficult because of nonlinearity and differences in fluid dynamics as scale becomes larger.</p> <p>Nonlinear scaling: if height to tank or impeller ratios are kept constant, volume increases much drastically compared to surface area. In animal-cell-culture bioreactors, this makes CO₂ removal an issue because of increased vessel height, pressure, and less liquid surface area at the top. Scaling up vessels also causes higher variation in shear-force and less efficient mixing because it takes longer for the liquid to circulate and more stagnant areas. Figure one shows the change in scale-up criterion that are dependent on tank diameter and impeller rotational speed. As seen in the table, each criterion changes differently in comparison to one another even though there is only one scale up from 80L to 10,000L. This is because each factor, such as power input, impeller-tip speed, and Reynold's number each have different dependencies on tank diameter and impeller rotational speeds. Gradients or stagnant zones can occur in larger bioreactors because mixing times increase. If mixing is inadequate, zones will have lower pH in areas like those near the base addition port, because of buildup of acidic products of cell metabolism like lactate. Oxygen concentrations can also be used up in areas that have nutrients concentrated. Carbon dioxide is also a byproduct of cell metabolism that gets harder to remove with larger scales. Unlike oxygen</p>

which requires a continuous flow, CO₂ is more soluble in media, allowing for it to dissolve and exit through the exit-gas stream. However, the decrease in surface area compared to volume diminishes the gas exchange that occurs on the surface of the liquid. This combined with higher hydrostatic pressure, which increases gas solubility, makes it more likely for dissolved CO₂ to build up in the vessel, causing pH changes or increasing osmolality. Maintaining constant mixing time is a common primary scale-up criterion because of the effects on pH/oxygen/substrate gradients. This criterion is dependent on impeller speed/agitation rate, impeller type/size, impeller spacing from the bottom of the vessel, and baffle design.

Research Question/Problem/Need

Scaling up bioreactor processes and designs are not linear in nature because of effects like changing fluid dynamics, and decreasing surface area to volume ratios that effect specific operation outcomes like gas-sparging rates, fluid homogeneity, etc.

Important Figures

Scale-Up Criterion	Designation	Small-Scale Bioreactor (80 L)	Production Bioreactor (10 ⁴ L)			
			Constant P/V	Constant Impeller Rotation (N)	Constant Tip Speed	Constant Re
Energy input	$P \propto N^3 D^5$	1	125	3,125	25	0.2
Volumetric energy input	$P/V \propto N^3 D^2$	1	1	25	0.2	0.0016
Impeller rotation	N	1	0.34	1	0.2	0.04
Impeller diameter	D	1	5	5	5	5
Impeller-pump rate	$Q \propto N D^3$	1	42.5	125	25	5
Circulation time	$t_c \propto V/Q$	1	2.94	1	5	25
Impeller-tip speed	$V \propto N D$	1	1.7	5	1	0.2
Reynold's number	$Re \propto N D^2$	1	8.5	25	5	1

Table 1: Interdependence of scale-up parameters; the "scale-up criterion" column indicates which variable is held constant between two scales. Table contents are adapted from Lara et al. (4).

VOCAB: (w/definition)

- Metabolite: a substance formed in or necessary for metabolism
- Gas-sparging: the process of bubbling gas (like air, nitrogen, or CO₂) through a liquid to remove unwanted dissolved gases or volatile substances, strip contaminants, improve mixing, or facilitate reactions
- Osmolality: the concentration of dissolved particles in a fluid
- Hydrostatic pressure: the force exerted by a fluid (like water) at rest due to gravity, increasing with depth and density
- Turbulence: chaotic, irregular fluid motion with unpredictable changes in velocity and pressure, characterized by eddies and swirls
- Oxygen-transfer rate: the speed at which oxygen moves from the gas into the liquid culture.

Article #19 Notes: Impeller Power Numbers in Closed Vessels

Source Title	Impeller Power Numbers in Closed Vessels
Source citation (APA Format)	Nienow, A. W., & Miles, D. (1971). Impeller Power Numbers in Closed Vessels. <i>Industrial & Engineering Chemistry Process Design and Development</i> , 10(1), 41–43. https://doi.org/10.1021/i260037a007
Original URL	https://doi.org/10.1021/i260037a007
Source type	Journal article
Keywords	Bioreactor, Fluid Dynamics, Reynolds Number, Power Number, Turbulent flow
#Tags	#Fluid Dynamics
Summary of key points + notes (include methodology)	<p>Data of experimental torque was collected based on multiple impeller designs and configurations. These designs had data collected on them across a range of impeller speeds that display data regarding laminar, transitional, and turbulent flow. In laminar flow cases, the power number decreased as Reynolds number increased. This was until a plateau was reached. This is expected because as power numbers increase, rotation speed becomes more and more effective at dissipating fluids rather than the relationship being linear. In transitional flow cases, flow begins to become unstable, making N_p less predictable and more dependent on impeller and tank geometry (makes sense because changes, even if they are small, to flow in eddies or loops can have large impacts on how efficiently mechanical energy is used. In turbulent flows, inertial fluid forces become much more dominant because of the high Reynolds number. Increasing impeller speeds do not have changes on overall fluid flow, except for the intensity of any turbulence. Because of this, N_p approaches a constant value that is mainly independent of Reynolds number because it is so high. Because of this, the N_p value would reflect the efficiency of the impeller and vessel geometry because they influence turbulence, showing why turbulent power numbers are widely used for scale-up</p>
Research Question/Problem/Need	How is power consumption related to and affected by bioreactor parameters (flow type, impeller geometry, and vessel design)?

Table showing various parameters in relation to impeller type and power numbers between 20,000 and 100,000 (turbulent flow). D/t is the ratio between impeller length (D) and tank width (T). Impeller clearance represents the impeller's vertical position. C represents the impeller's distance from the tank bottom to the impeller and Z represents total liquid height

VOCAB: (w/definition)

Power number (Np): dimensionless number of how much/efficiently mechanical energy a bioreactor's rotating impellers transfer to the fluid or media

Reynold's number (Re): dimensionless number that compares inertial forces to viscous forces in order to show what type of fluid flow is in a bioreactor

Keywords	CFD, eddy diffusivity, velocity profile, shear rate, torque, power, impellers, mixing, stirred vessel
#Tags	#Bioreactor, #CFD
Summary of key points + notes (include methodology)	<p>Stirred vessel bioreactors are mixing vessels used for cell culture. The mixing process and dynamics inside the vessel are important for effective cell culture. Creating models of fluid dynamics inside the vessel can allow for visualizations of the components of the bioreactor and estimations of its efficiency. Despite this, several parameters of measurements of the system need to be taken, the process can take extremely long to collect enough data, and it may be difficult to collect experimental information in some areas of the bioreactor, causing only average result values to be collected.</p> <p>Computational Fluid Dynamics (CFD) models have been an advancement that can be used in place of other models. ACFD model is a simulation that is less time consuming, cheaper compared to physical models, and can visualize the system three dimensionally.</p> <p>A CFD model was constructed to model the mixing process of lysogenic broth medium, which is intended for cultivation of <i>E. coli</i>, in a 5 liter bioreactor. Model construction started with dimensional parameters of the vessel. Fluid properties were input into the software to mirror water, and the mixing rate was set at 300rpm. Navier-Stokes equations were used to predict</p>

fluid velocity and pressure inside the bioreactor. The mesh of the CFD model was set with medium-coarse size tetragonal elements to minimize computing needs. After simulating the process with double pitch blades and Rushton type impellers numerous figures were produced visualizing velocity, pressure, mesh effectiveness, mixing through eddy motion, and shear rate of the fluid. Graphs were also made showing power drawn and revolutions per minute of models including pitch blades and rushton type impellers.

Research Question/Problem/Need
 To investigate the mixing phenomena of a stirred vessel bioreactor through a theoretical computer simulation model.

VOCAB: (w/definition)

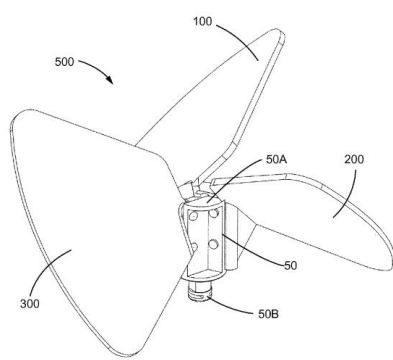

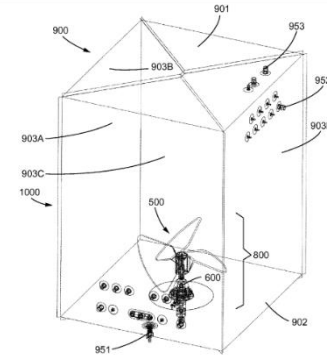

Mixing phenomena: processes where different substances combine, driven by mechanisms like bulk transport, turbulent flow ([eddy diffusion](#)), and molecular diffusion

Phase: a distinct, uniform region of a substance with consistent physical and chemical properties

	<p>Phase homogeneity: the uniform composition and structure of a single-phase system, where components are completely mixed without any visible boundaries between them</p> <p>Baffles are vanes, plates, or panels installed inside a vessel to obstruct and redirect the flow of a liquid or gas</p> <p>Decoction: the liquor resulting from concentrating the essence of a substance by heating or boiling, especially a medicinal preparation made from a plant</p>

Source type	Patent
Keywords	Bioreactor, Impeller, CFD, Shear stress
#Tags	#CFD
Summary of key points + notes (include methodology)	Standard impeller designs can result in stagnant zones, inefficient oxygen and nutrient transfer, and high shear near impeller blades. To address this, an experimental impeller shape was simulated in CFD to analyze velocity, shear stress, and energy dissipation. CFD was used in order to skip the physical process of trial and error testing and the simulations would be able to be translated over into real-world performance. The design is shown to provide uniform fluid mixing. Highlighted advantages include a blade notch design which allows for flexibility of what blade type to use if the need arises. The design is also described to be operable in different biocontainer makeups. This can be applied towards cell culture mixing, media solution preparation, buffer or reagent mixing, pharmaceutical fluid blending, as well as food bioprocess situations.
Research Question/Problem/Need	To optimize bioreactor impeller geometry with CFD to improve mixing and decreasing shear stress

Patent #2 Notes: Guide flow cylinder, cylindrical bioreactor using guide flow cylinder and method for arranging guide flow cylinder

Source Title	Guide flow cylinder, cylindrical bioreactor using guide flow cylinder and method for arranging guide flow cylinder
Source citation (APA Format)	You, X., Wang, L., Ji, Min. (2012). <i>Guide flow cylinder, cylindrical bioreactor using guide flow cylinder and method for arranging guide flow cylinder</i> (Patent No. CN102517212A). USPTO. https://patents.google.com/patent/CN102517212A/en
Original URL	https://patents.google.com/patent/CN102517212A/en
Source type	Patent
Keywords	Bioreactor, guide flow, fluid flow,
#Tags	#Bioreactor, #Fluid Dynamics
Summary of key points + notes (include methodology)	Traditional guide tubes in airlift bioreactors that are straight and smooth only give basic circulation and limited gas-liquid mixing. This means they are not especially optimal for radial mixing. At increasing aeration rates, these tubes can result in unwanted high fluid velocity and turbulence, resulting in excessive shear. Instead of a straight guide tube, this patent is a guide flow cylinder, with a wave-shaped surface running vertically through the vessel tank with openings on the top and bottom. These openings and wave shape are intended for smoother fluid entry and exit to minimize sudden changes in direction. This design allows for overall increased mixing/distribution because of the waves which break up stagnant areas more frequently as fluids move in the vessel. This effective mixing allows for better gas exchange for oxygen and CO ₂ . Finally, shear stress is reduced as well because this mixing is achieved without increasing gas velocities.
Research Question/Problem/Need	To design a more optimal method of for increasing mixing efficiency and mass transfer in cylindrical airlift bioreactors

<p>Important Figures</p>	 <p>Figure 5 is the design of a bioreactor containing the guide flow cylinder for improved bioreactor performance</p>
