## Knowledge Gaps:

This list provides a brief overview of the major knowledge gaps for this project, how they were resolved and where to find the information.

Knowledge Gap	Resolved By	Information is located	Date resolved
Background information on current biotech innovations on tooth regeneration	Reading an article on tooth repair and regeneration technology and methods	Article #2	August 15, 2024
Different ways that tooth regeneration can be triggered	Article on mesenchymal stromal cell exosomes and how they aid in tooth regeneration	Article #3	September 3, 2024
Different ways that tooth regeneration can be triggered	Article on the use of CNCLCs to replicate dental pulp tissue and how the process of CNCLC regeneration can be triggered by angiogenic hydrogel	Article #4	September 14, 2024
Use of exosomes on different activity of hDPSCs	Article on exosomes from adipose-derived stromal-vascular fraction and how they play a role on the migration activity of hDPSCs	Article #5	September 14, 2024
How dental pulp regeneration even begins	Learned more about the different signalling pathways and how they affect dental pulp / oral health overall	Article #6	September 22, 2024
Different materials that could help with stem cell tissue regeneration	Studied the role of basic fibroblast growth factors in dental pulp stem cell tissue regeneration	Article #7	September 22, 2024
Specifics on signalling pathways that could	Read up on the role of Wnt signalling pathway in generating more tissue	Article #8	September 23, 2024

help with regenerative medicine as a whole	(how if it's too active, it leads to cancer, too inactive, leads to too little regeneration)		
More on different signalling pathways	Read an article that reviewed 6 different signalling pathways and how they affect oral health	Article #9	September 29, 2024
Details on the Wnt signalling pathway and its specific applications in dentistry	Read up on how it works to regenerate dentin	Article #10	October 6, 2024
Details on the Wnt signalling pathway and its specific applications in dentistry	Read on how non-Canonical Wnt Jagged1 proteins help with osteo/odontogenic differentiation of hDPSCs	Article #11	October 6, 2024
How are planaria used in regenerative medicine research and why	Read an article that discusses the regenerative abilities of planaria + recent discoveries made using planaria	Article #12	October 27, 2024
The effects of Wnt signalling in Planaria specifically (does it even exist in planaria?)	Read an article on its applications in planaria + how recent research has been conducted and yielded answers to questions that researchers had regarding Wnt	Article #13	October 27, 2024
What different chemicals / proteins / other help with the activation of Wnt signalling?	Read an article on the effects of lithium chloride on activating the Wnt signalling pathway + regeneration	Article #14	November 3, 2024
What different chemicals / proteins / other help with the	Read a review article on different modulators of the Wnt signalling	Article #15	November 3, 2024

activation of Wnt signalling?	pathway that aid in dental regeneration		
How can NP928 help with dental regeneration?	Read an article that described the benefits of NP928 as a GSK3-inhibitor on inducing dentinogenesis	Article #16	November 10, 2024
How to measure the blastema growth of the planaria	Read an article on Fiji/ImageJ technology and how to quantify blastema growth using the software	Article #17	November 10, 2024
What different Wnt inhibitors exist? What would they be used for?	Read an article on the inhibitors of Wnt and how they help with tumor treatment	Article #18	November 17, 2024
How does enamel regeneration work?	Read an article on DESCs and how they function to help with the regeneration of enamel	Article #19	November 17, 2024
How does Wnt3A help with dental regeneration?	Read an article on Wnt3A proteins and how they have been shown to aid in dental regeneration by activating the Wnt signalling pathway	Article #20	November 17, 2024
What are some other ways of regenerating the dental pulp?	Read an article on how miR-335-5p helps in modulating osteogenic differentiation	Article #21	November 20, 2024

## Literature Search Parameters:

These searches were performed between 15/08/2024 and 06/10/2024.

List of keywords and databases used during this project:

Database/search engine	Keywords	Summary of search
Google Scholar	Tooth Regeneration	Articles give quick reviews of tooth regeneration thus far and talk about why tooth repair / regeneration should be the next focus, as current solutions to tooth decay and tooth loss are not very practical and can cause greater harm in the future.
PUB Med	Dentin regeneration	Articles were about different and current methods of dentin regeneration, most by the usage of stem cells
PUB Med	Dental pulp tissue	Articles found were on different dental pulp tissue regeneration and preservation methods, with the article I read being on how a specific cell can replicate dental pulp tissue
PUB Med	Wnt Signalling dentistry	Most articles were old, but most of them provided information on how research was conducted to see the effectiveness of the Wnt signalling pathway in regenerative dentistry
PUB Med	Planaria	Articles about studies conducted using planaria, mostly focused on regenerative abilities of planaria / how research has advanced since then

<b>Summary of key points + notes (include methodology)</b>	The researcher created a biomaterial that can be used in filling or sealing tooth and bone cavities. Several calcium-based compounds were mixed with water while phosphate compounds were prepared, and when mixed, this creates hydroxyapatite. The biomaterial can help stimulate hard / soft tissue healing, generation, or regeneration.
<b>Research Question/Problem / Need</b>	Create a biomaterial that can be used to seal or fill tooth and bone cavities and that can stimulate hard / soft tissue healing, generation, or regeneration.
<b>Important Figures</b>	 <p>The diagram illustrates a cross-section of a tooth with a root embedded in the jawbone. A dental filling is shown in the crown, and a cavity in the root is filled with a biomaterial. Labels indicate 'Dental Filling Material' and 'Cavity Filled with Blood and Biomaterial'. The caption below the diagram is 'Fig 15'.</p>

## Article #2 Notes: Tooth Repair and Regeneration

<b>Source Title</b>	Springer Link
<b>Source citation (APA Format)</b>	Angelova Volponi, A., Zaugg, L.K., Neves, V., Liu, Y., & Sharpe, P. T. (2018). Tooth Repair and Regeneration. <i>Current Oral Health Reports</i> , 5, 295–303. <a href="https://doi.org/10.1007/s40496-018-0196-9">https://doi.org/10.1007/s40496-018-0196-9</a>

<b>Source type</b>	Science Journal
<b>Keywords</b>	Tooth Repair, Tooth Regeneration, Whole-Tooth Bioengineering, Organogenesis
<b>#Tags</b>	#Intro #BackgroundInfo #GeneralInfo
<b>Summary of key points + notes (include methodology)</b>	This review analyzes the different ways in which the field of tooth regeneration has advanced in the past, studying the three approaches of enamel mineralization, whole tooth engineering, and the biological repair of dentin. While osseointegrated dental implants revolutionized dentistry in the past, they lack the periodontal ligament that protects against the mastication force that could cause jawbone resorption, so they aren't sustainable in the long run to a person's oral health. Advances in restorative dentistry focus on repairing or regenerating the tooth enamel and dentine-pulp complexes using biomimetic methods and stem cell therapies, as well as working towards whole tooth bioengineering.
<b>Research Question/Problem/Need</b>	How has tooth repair and regeneration technology and methods advanced over the past couple of years?
<b>Important Figures</b>	Figure B – shows process of bioengineered tooth implant
<b>VOCAB: (w/definition)</b>	Wnt/ $\beta$ -catenin signaling pathway – biological pathway of cell development and repair. Activating this can stimulate formation of new dentin and support the repair and regeneration of dental tissues, including reactionary and reparative dentine Ameloblasts – cells responsible for forming dental enamel. During tooth development, ameloblasts are active in producing enamel but go through a programmed cell death once the enamel has fully matured, making the enamel incapable of natural repair Odontoblasts – cells in the dental pulp responsible for dentin formation. Can secrete new dentin as part of the tooth's natural repair processes, including reactionary and reparative dentine formation
<b>Cited references to follow up on</b>	Yang L, Angelova Volponi A, Pang Y, Sharpe PT. Mesenchymal cell community effect in whole tooth bioengineering. <i>J Dent Res</i> . 2017;96(2):186–91. <a href="https://doi.org/10.1177/0022034516682001">https://doi.org/10.1177/0022034516682001</a> . This original research work explores the cell community effect on mesenchymal cells as a tool to "rescue" the odontogenic potential of cultured cells that is lost in vitro.

**Follow up Questions**

How could the genetic mechanisms in humans be modified to enable the growth of additional permanent teeth beyond the typical one tooth? (more specifically for cells like ameloblasts)

How could periodontal ligament be integrated in bioengineered teeth to avoid jawbone resorption?

How can bioprinting be used to help with the regeneration or bioengineering of teeth?

## Article #3 Notes: Mesenchymal stromal cell exosomes enhance dental pulp cell functions and promote pulp-dentin regeneration

<b>Source Title</b>	Science Direct
<b>Source citation (APA Format)</b>	Shi, J., Teo, K. Y. W., Zhang, S., Lai, R. C., Rosa, V., Tong, H. J., Duggal, M. S., Lim, S. K., & Toh, W. S. (2023). Mesenchymal stromal cell exosomes enhance dental pulp cell functions and promote pulp-dentin regeneration. <i>Biomaterials and Biosystems</i> , 11. <a href="https://doi.org/10.1016/j.bbiosy.2023.100078">https://doi.org/10.1016/j.bbiosy.2023.100078</a>

<b>Source type</b>	Science Journal
<b>Keywords</b>	Pulp-dentin regeneration, mesenchymal stromal cell exosomes, mesenchymal stromal cells, exosomes, stem cells, mesenchymal stem cell therapy, MSCs
<b>#Tags</b>	#Pulp-dentinRegeneration #Exosomes
<b>Summary of key points + notes (include methodology)</b>	<p>The researchers explored how exosomes from mesenchymal stromal cells can help with the reparation of dental pulp by improving the migration, growth, and specialized cell functions of dental pulp cell. These effects are achieved by specific signaling pathways that are activated by exosomes. The study shows that MSC exosomes can promote the formation of dentin-like tissue and repair dental pulp in various models.</p> <p>Methodology: MSC exosomes were prepared from an immortalized E1-MYC 16.3 line derived from human embryonic stem cells (hESCs). Dental pulp cells were isolated from the extracted incisors of 8-week-old female Sprague-Dawley rats. DPCs were treated with different concentrations of exosomes or control solutions. Viability was assessed using MTS and DNA content measurements. Apoptosis in DPCs was evaluated using Annexin V and propidium iodide staining, analyzed by flow cytometry. The migration of DPCs in response to exosome treatment was measured using a transwell system. To study the signaling pathways activated by exosomes, DPCs were pre-treated with various inhibitors before exosome treatment. Effects on the involvement of adenosine receptors and the signaling pathways AKT and ERK were analyzed. In animal models, pulp defects or human premolar roots were treated with exosomes or controls. The data was then analyzed using statistical tests to determine the significance of different experimental conditions</p>
<b>Research Question/Problem/ Need</b>	How can exosomes from MSC therapy enhance dental pulp cell regeneration?

<p><b>Important Figures</b></p>	<p>Graphical abstract</p>
<p><b>VOCAB: (w/definition)</b></p>	<p>MSC - Mesenchymal stromal cells (MSCs) are a type of adult stem cell found in various tissues, including bone marrow, fat, and umbilical cord blood.          Exosomes - Exosomes are tiny, membrane-bound vesicles released by cells into the extracellular space.</p>
<p><b>Cited references to follow up on</b></p>	<p>Preliminary study on dental pulp stem cell-mediated pulp regeneration in canine immature permanent teeth          J Endod, 39 (2) (2013), pp. 195-201, 10.1016/j.joen.2012.10.002          Challenges and advances in clinical applications of mesenchymal stromal cells          J Hematol Oncol, 14 (1) (2021), p. 24, 10.1186/s13045-021-01037-x</p>
<p><b>Follow up Questions</b></p>	<p>What specific molecular mechanisms are involved in the activation of the AKT and ERK signaling pathways by MSC exosomes in dental pulp cells? Are there additional signaling pathways or molecular interactions that could also play a role in the observed effects?</p>

## Article #4 Notes: iPSC-derived cranial neural crest-like cells can replicate dental pulp tissue with the aid of angiogenic hydrogel

<b>Source Title</b>	ScienceDirect
<b>Source citation (APA Format)</b>	Kobayashi, Y., Nouet, J., Baljinnyam, E., Siddiqui, Z., Fine, D. H., Fraidenaich, D., Kumar, V. A., & Shimizu, E. (2022). iPSC-derived cranial neural crest-like cells can replicate dental pulp tissue with the aid of angiogenic hydrogel. <i>Bioactive Materials</i> , 14, 290–301. <a href="https://doi.org/10.1016/j.bioactmat.2021.11.014">https://doi.org/10.1016/j.bioactmat.2021.11.014</a>
<b>Original URL</b>	<a href="https://www.sciencedirect.com/science/article/pii/S2452199X21005351">https://www.sciencedirect.com/science/article/pii/S2452199X21005351</a>
<b>Source type</b>	Scientific Journal
<b>Keywords</b>	Dental pulp tissue, iPSC-derived cranial neural crest-like cells
<b>#Tags</b>	#DentalPulpRegeneration
<b>Summary of key points + notes (include methodology)</b>	<p>CNCLCs were used to replicate the characteristics of dental pulp tissue by improving a process that previously existed that used iPSCs. They showed significant odontoblast differentiation ability, particularly when treated with FGFs. A mouse subcutaneous model was used to exhibit the replication of the CNCLCs to the dental pulp tissue characteristics. This was induced by SAPH (angiogenic self-assembling peptide hydrogel) SLan, which is a versatile biocompatible scaffold.</p> <p>SLan was synthesized and prepared using standard solid-phase procedures and purified. Human iPSCs were obtained from human gingival fibroblasts collected from the gingival connective tissue connected to extracted third molars. Root fragments from third molars were prepared and implanted with labeled cells into mice, and after 8 weeks, histological analysis was conducted to assess the pulp regeneration. It was found that the most well-established method for generating neural crest (NC)-like cells from iPSCs involves activating the Wnt signaling pathway. The study shows the success of combining regenerative science with SAPH technology.</p>
<b>Research Question/Problem/ Need</b>	How can the previously existing method for CNCLC replication of dental pulp tissue be improved upon using SLan and SAPH technology?

<p><b>Important Figures</b></p>	<p>The diagram illustrates a multi-step process for generating dental pulp tissue. It begins with iPSCs, which are differentiated into CNC-like cells. This process involves the inhibition of the TGFβ-SMAD pathway and the activation of the Wnt1 pathway by inducing iNSCs. The resulting CNC-like cells are then labeled with a lentiviral Tomato vector and undergo osteogenic differentiation with PDGFs, mixed with an angiogenic hydrogel, to form a cell-gel complex. This complex is used to fill a root canal in a wisdom tooth (third molar) after it has been prepared (trimmed to 1-cm long, root canal instrumentation, radicle hyperbolic treatment, and rinsed with EDTA solution). The tooth is then placed in a cement cap. The cell-gel complex is also implanted into the subcutaneous space of an NSG mouse. Finally, histological analysis is performed on the tooth and mouse tissue to study the healing and formation of pulp and bone.</p>
<p><b>VOCAB: (w/definition)</b></p>	<p>Peptides – short chains of amino acids linked by peptide bonds.</p>
<p><b>Cited references to follow up on</b></p>	<p><a href="https://www.frontiersin.org/journals/bioengineering-and-biotechnology/articles/10.3389/fbioe.2020.00475/full">https://www.frontiersin.org/journals/bioengineering-and-biotechnology/articles/10.3389/fbioe.2020.00475/full</a></p>
<p><b>Follow up Questions</b></p>	<p>How do different designs of angiogenic hydrogels affect the replication and functionality of CNCLCs and thus dental pulp tissue?</p>

<b>Source type</b>	Scientific Journal
<b>Keywords</b>	Exosomes, dental pulp stromal cells
<b>#Tags</b>	#DentalPulpRegeneration #Exosomes
<b>Summary of key points + notes (include methodology)</b>	As a response to injury in the dental pulp, DPSCs begin to migrate to the area, a process which is heavily dependent on microenvironmental signals. Exosomes have been found to carry and maintain bioactive proteins that help with cell communication which can enhance the DPSC migration, and the researchers have found that AD-SVF is a good source of exosomes. The researchers isolated the AD-SVF using size exclusion chromatography (SEC) and characterized it by using flow cytometry assays and Nanoparticle Tracking Analysis (NTA). The hDPSCs were exposed to the AD-SVF and cultivated until 80% confluence and third to fourth passage by using a control of 0% exposure and two experimental quantities of 0.1% and 1% AD-SVF exposure, and measured at intervals of 6, 24, and 48 hours. The data was analyzed using the Friedman ( $p < 0.001$ ) and Kruskal Wallis ( $p < 0.05$ ) test, and it was found that the wound area decreased after being exposed to the 0.1% and 1% AD-SVF Exo, showing that the hDPSC migration increased as a result of the applied AD-SVF Exo, with the highest result being found at 0.1% exposure.
<b>Research Question/Problem/ Need</b>	How is hDPSC migration affected by AD-SVF Exo?

<p><b>Important Figures</b></p>	<p>(A) and (B) are phase-contrast micrographs of cells in culture, each with a 100 μm scale bar. (C) consists of four flow cytometry histograms for DPSC Normal 221228-Cocktail. The top-left histogram shows CD90+ cells (FITC-A) with a peak around 10<sup>4</sup>. The top-right histogram shows Lin- cells (PE-A) with a peak around 10<sup>2</sup>. The bottom-left histogram shows CD105+ cells (PerCP-Cy5-5-A) with a peak around 10<sup>3</sup>. The bottom-right histogram shows CD73+ cells (APC-A) with a peak around 10<sup>4</sup>.</p>
	<p>Results of the hDPSCs during third and fourth passages compared with after 24-hour starvation</p>
<p><b>VOCAB: (w/definition)</b></p>	<p>Adipose-derived – derived from body fat (adipose tissue)          Stromal-vascular fraction – a mixture of stromal cells (supportive cells that provide structure to the tissue) and vascular cells (cells related to blood vessels)</p>

<b>Source type</b>	Science Journal
<b>Keywords</b>	Signaling pathways, dental pulp regeneration, stem cells
<b>#Tags</b>	#DentalPulpRegeneration #SignallingPathways
<b>Summary of key points + notes (include methodology)</b>	The research paper aimed to explore signaling pathways that regulate dental stem cell regeneration. In order to explore the different pathways, researchers used three different methods – drug delivery, genetic modification, and physical stimulation. They found that key cytokines and growth factors are important in migration and proliferation of stem cells and odontogenic differentiation. They also found that transplanting dental stem cells with growth factors can help regenerate vascularized pulp-like tissues.
<b>Research Question/Problem/ Need</b>	How can growth factors help dental stem cells regenerate tooth pulp?
<b>Important Figures</b>	<p style="text-align: center;"><b>Stem cell-based dental pulp regeneration: insights from signaling pathways</b></p> <p style="text-align: center;">WNT, BMP, FGF, TGF</p> <p style="text-align: right;">Graphical abstract</p>

<b>Summary of key points + notes (include methodology)</b>	The researchers investigated how basic fibroblast growth factors play a role in cell proliferation, differentiation, and extracellular matrix turnover of dental pulp stem cells. They also explored their involvement in the MEK/ERK signaling pathway. hDPSCs were cultured and studied for FGFR expression using RT-PCR. Cell proliferation was measured using MTT assay, and differentiation was assessed using alkaline phosphatase (ALP) activity. The researchers found that the hDPSCs express both FGFR1 and FGFR2, with bFGF helping cell viability at specific concentrations but reducing ALP activity at higher doses. This means that bFGF can help in dental pulp cell regeneration.
<b>Research Question/Problem/ Need</b>	How can bFGFs help with dental pulp regeneration?

<b>#Tags</b>	#WntSignallingPathway
<b>Summary of key points + notes (include methodology)</b>	<p>Researchers are interested in the applications of activating and inhibiting the Wnt signalling pathway to help with regeneration as well as to help fight cancer. Wnt is a group of proteins that are responsible for cell communication by helping cells grow, divide, and function.</p> <p>The researchers tested different materials to see what triggers and what inhibits Wnt. The methods they used were high throughput screening, luciferase reporter assays, in vitro and in vivo models, and structural and genetic studies. A high throughput screening is a test that tests large libraries of compounds to see what inhibits and what activates a signalling pathway. A luciferase reporter assay is an assay that measures the activity of Wnt/<math>\beta</math>-catenin signaling by quantifying luminescence from reporter genes activated by <math>\beta</math>-catenin. The in vitro and in vivo models tested the biological effects of Wnt modulators, the structural studies used crystallography to see how Wnt antagonists react with their receptors, and the genetic studies investigated the genetic mechanisms regulating Wnt signaling and its modulators. They also used a TOPFlash assay, which measured the Wnt/<math>\beta</math>-catenin signaling activity.</p> <p>The researchers used activation strategies like monoclonal antibodies, <b>R-Spondin proteins</b> (which probably have applications in regenerative medicine), and small molecule inhibitors, like SFRP-1 Inhibitors (which helps with bone formation) and NOTUM Inhibitors (which may help with treating osteoporosis).</p>
<b>Research Question/Problem/ Need</b>	What different materials can inhibit or activate the Wnt signalling pathway and why?

## Article #9 Notes: Effects of different signaling pathways on odontogenic differentiation of dental pulp stem cells: a review

<b>Source Title</b>	National Library of Medicine
<b>Source citation (APA Format)</b>	Zhou, L., Zhao, S., Xing, X. (2023) Effects of different signaling pathways on odontogenic differentiation of dental pulp stem cells: a review. <i>Frontiers in Physiology</i> , 14. <a href="https://doi.org/10.3389/fphys.2023.1272764">https://doi.org/10.3389/fphys.2023.1272764</a> .
<b>Original URL</b>	<a href="https://www.ncbi.nlm.nih.gov/pmc/articles/PMC10622672/">https://www.ncbi.nlm.nih.gov/pmc/articles/PMC10622672/</a>
<b>Source type</b>	Journal Article
<b>Keywords</b>	Wnt signalling pathways, DPSCs
<b>#Tags</b>	#WntSignallingPathway #SignallingPathways
<b>Summary of key points + notes (include methodology)</b>	<p>The researchers tested different types of signalling pathways to see their effects on odontogenic differentiation.</p> <p>The canonical pathways of the Wnt signalling pathway involved <math>\beta</math>-catenin activation for odontogenic differentiation. The non-canonical pathways, such as PCP and Wnt/Ca<sup>2+</sup>, functioned independently of <math>\beta</math>-catenin. There have been mixed effects on odontogenic differentiation, though, with some studies showing that <math>\beta</math>-catenin enhances differentiation and expression of proteins like Runx2, while others show that it inhibits the process. Wild-type SATB2 helps the odontogenic differentiation via Wnt/<math>\beta</math>-catenin signaling, whereas overexpression of Wnt10A and certain Wnt proteins can suppress it.</p> <p>The BMP/Smad signaling pathways help facilitate the expression of genes like DSPP, DMP-1, ALP, and OCN, and inhibiting these expressions can lead to tooth development disorders and harm dentin regeneration. Studies show that factors like leptin and epiregulin promote the odontogenic differentiation of dental pulp stem cells (DPSCs) by activating the MAPK signalling pathways, which leads to increased expression of differentiation markers such as ALP, DSPP, and Runx2. The NF-<math>\kappa</math>B signalling pathways help with cell proliferation and immune responses, and estrogen deficiency can impair their effects on DPSC differentiation while inhibiting the pathway can increase the differentiation potential. The PI3K/AKT/mTOR signalling pathways are important for cell growth and metabolism, with activated AKT promoting cell survival and differentiation, and inhibiting these pathways can also increase the differentiation potential of DPSCs. The Notch signalling pathway regulates cell differentiation through the interactions between Notch receptors and ligands, with different effects on DPSCs.</p>
<b>Research Question/Problem/ Need</b>	How do different signalling pathways affect odontogenic differentiation of DPSCs?

<b>#Tags</b>	#WntSignalling, #DentalPulpRegeneration
<b>Summary of key points + notes (include methodology)</b>	<p>Wnt proteins act as ligands in the Wnt signalling pathway. Receptors like Frizzled and low-density lipoprotein receptors (LRP) help carry out signal transduction, and there are several activators and inhibitors that modulate that signalling.</p> <p>In the canonical pathway Wnt ligands activate receptors and stabilize <math>\beta</math>-catenin, which then moves to the nucleus to start gene expression related to Wnt signalling. Non-canonical pathways, on the other hand, operate independently of <math>\beta</math>-catenin and help with processes like calcium signalling and planar cell polarity, which influences cellular that are important for development.</p> <p>Tooth development depends on the interactions between dental epithelium and mesenchyme. Wnt signalling plays an important role in various stages of this process, including in the tooth initiation and cell differentiation. Experiments show that mice with stabilized <math>\beta</math>-catenin produce more dentin, although the dentin had a different structure, which proves that excessive Wnt signalling can lead to increased dentin production. The Wnt pathway also affects the epigenetic regulation of dental pulp stem cells through mechanisms like DNA methylation and histone modification.</p>

<b>#Tags</b>	#Non-CanonicalWntSignalling #DentalPulpRegeneration #NotchSignalling
<b>Summary of key points + notes (include methodology)</b>	Immobilized Jagged1 proteins were used to seed hDPSCs, which were then maintained in osteo/odontogenic medium for 3, 7, and 14 days. Significantly enhanced mineral deposition was noted after Jagged1 was used to treat the tooth, which proves that activating the Notch signalling pathway can promote osteo/odontogenic differentiation of hDPSCs in vitro. It was also found that DAPT effectively inhibited Notch signalling. The treatment to a tooth by non-canonical Wnt protein, Wnt5A, promoted mineralization.
<b>Research Question/Problem/ Need</b>	How does Wnt signalling help with osteo/odontogenic differentiation in hDPSCs?

<b>Source type</b>	Review Journal Article
<b>Keywords</b>	Planaria, Wnt Signalling
<b>#Tags</b>	#Planaria #WntPlanaria
<b>Summary of key points + notes (include methodology)</b>	The regenerative properties of planaria are mostly due to neoblasts. Planarian stem cells are regarded as heterogeneous cells characterized by a high ratio of nucleus to cytoplasm. After injury, over 200 genes are activated, but the missing-tissue response (MTR) is specifically induced only by tissue loss, such as during amputation. The gene <i>Smed-follistatin</i> has been identified as crucial for MTR, as it regulates regeneration speed and is only expressed in response to injury, not during homeostasis. Blocking follistatin prevents successful regeneration and disrupts the re-establishment of the anterior-posterior (A/P) axis by negatively regulating Wnt signaling, which is vital for head regeneration. Wnt helps with head regeneration, so inhibiting Wnt signalling after an amputation can result in the regeneration of tails in the wrong places. Disruption of bioelectric networks can cause permanent morphological abnormalities.
<b>Research Question/Problem/Need</b>	What is currently known about planarian regeneration?
<b>Important Figures</b>

<b>Keywords</b>	Planaria, Wnt1, RNAi
<b>#Tags</b>	#Planaria #WntSignallingPathway
<b>Summary of key points + notes (include methodology)</b>	<p>Wnt signalling pathway split (like canonical vs. non-canonical due to <math>\beta</math>-catenin involvement) is sort of artificial but can be useful in context-specific result. Schmidtea mediterranea is valuable in studying Wnt because of their regenerative abilities. Wnt genes show distinct expression regions – for example, wnt1 is localized in the posterior dorsal midline, while wnt11-1 and wnt11-2 are expressed in the tail. Silencing Wnt genes through RNA interference (RNAi) produces many different phenotypes. Wnt1, when silenced, can lead to “two-headed” or “tailless” phenotypes, indicating its role in canonical Wnt signaling. Wnt11-2 also contributes to tail morphology but does not affect polarity reversal. Wnt1 is the first to express after amputation, and its response is free of stem cells. The interaction among Wnt ligands is crucial for proper AP patterning. It is proposed that wnt1 and wnt11-5 work together through <math>\beta</math>-catenin to control posterior identity. The Hedgehog (Hh) signaling pathway may also influence Wnt activation during regeneration, with evidence suggesting Hh acts upstream of <math>\beta</math>-catenin. The planarian homolog of Notum, a secreted hydrolase, is crucial for establishing anterior-posterior (AP) polarity. It is upregulated at anterior wounds shortly after amputation and inhibits posterior specification. Silencing notum leads to “two-tailed” planarians. A coherent model for early AP fate decisions suggests that wnt1 activation leads to <math>\beta</math>-catenin-1 activation and subsequently influences genes like wnt11-5 and notum. In anterior wounds, Notum and sFRP-1 inhibit Wnt signaling to facilitate head differentiation, while in posterior wounds, wnt1 is maintained, activating additional downstream targets. Wnt5, the only described non-canonical Wnt in planarians, is implicated in controlling neural connectivity and limiting the growth of the nervous system along the medio-lateral axis.</p>
<b>Research Question/Problem/</b>	How do Wnt signalling pathways influence axial polarity and cell fate

<b>Need</b>	decisions during the regeneration of Schmidtea mediterranea?

<b>Source type</b>	Journal Article
<b>Keywords</b>	Lithium chloride, dentin regeneration, transdifferentiation, topical agent
<b>#Tags</b>	#LiCl #WntSignalling #DentinRegeneration #Methodology
<b>Summary of key points + notes (include methodology)</b>	The researchers focused on activating the canonical Wnt signalling pathway to trigger the natural process of dentinogenesis. They removed the coronal (or crown) and pulp of the molar and applied the activator lithium chloride. The goal was to encourage transdifferentiation towards odontoblasts from the surrounding pulpal cells. MicroCT proved that LiCl succeeded in inducing dentin repair and even the formation of a dentin bridge. They tested on mice and applied LiCl as a topical agent by mixing it with material carriers (macrogol and propylene glycol in a 1:1 ratio) to achieve a concentration of 10 mM LiCl. The cavity was then coated with a bonding agent and cured for 20 seconds. Three-dimensional images of the tooth structure were obtained using a Microfocus X-ray CT system at specific voltage and current settings. The images were reconstructed at a spatial resolution of 17 µm and processed with VG Studio MAX 2.0 software. Teeth and surrounding bone were fixed in 4% paraformaldehyde overnight, decalcified in 12.5% EDTA for three weeks, dehydrated, embedded in paraffin, and sectioned at 7 µm for hematoxylin and eosin staining. Frozen sections (10 µm) were also prepared for in situ hybridization. Digoxigenin-labeled RNA probes were used for in situ hybridization to detect gene expression, with the preparation of Dspp RNA probes referenced from previous studies. Quantitative comparisons were made using the Mann-Whitney U test, with significance defined at $p < 0.05$ .
<b>Research Question/Problem/Need</b>	How can lithium chloride be used in vivo to help aid in Wnt-induced dentin regeneration?

#Tags	#WntSignalling #Planaria #NP928 #Wedelolactone #Methodology
Summary of key points + notes (include methodology)	Dental caries leading to pulp exposure is treated with inorganic calcium-containing materials like calcium hydroxide (CH), mineral trioxide aggregate (MTA), and Biodentine, which help in forming new dentin from odontoblast-like cells derived from resident stem cells in the pulp. GSK3 inhibitors can help improve reparative dentin formation. Tideglusib is a well-studied GSK3 inhibitor that upregulates Wnt activity and promotes dentin regeneration but has low solubility, and so <b>NP928</b> is a modified version of it. Tivantinib, another small molecule, inhibits GSK3 and has low toxicity in dental pulp cells, but requires further investigation in vivo. Lithium chloride (LiCl) also inhibits GSK3 and has been shown to stimulate reparative dentin formation. R-spondin 2 is a Wnt agonist that enhances odontogenic differentiation in dental pulp stem cells (DPSCs) by activating Wnt/ $\beta$ -catenin signaling, increasing expression of key odontogenic markers. <b>Wedelolactone</b> is a natural compound that helps promote odontoblast differentiation and mineralisation in DPSCs by enhancing $\beta$ -catenin nuclear accumulation and expression of odontoblast-related genes.
Research Question/Problem/Need	What modulators can help activate the Wnt signalling pathway to help with dental pulp regeneration?

<b>Important Figures</b>	 <p>The diagram illustrates two pathways for dental pulp regeneration following pulp exposure. In the top pathway, a hydrogel is applied to the exposed pulp, followed by sealing and drug release, leading to restoration. In the bottom pathway, a sponge is applied to the exposed pulp, followed by sealing and drug release, leading to restoration. Both pathways involve the application of molecules that enhance Wnt/β-catenin signaling.</p>

<b>#Tags</b>	#NP928 #Methodology #DentinRegeneration #WntSignalling
<b>Summary of key points + notes (include methodology)</b>	Researchers developed a small-molecule drug that targets GSK3 to inhibit it and stimulate reparative dentine formation. This drug belongs to thiazolidinone (TDZD) family of drugs and has similar properties to tideglusib, but unlike the other drugs of the family, NP928 is more water soluble and thus can be directly delivered to pulp lesions. It can be part of a biodegradable hydrogel (Methacrylate (MA)–hyaluronic acid (HA) hydrogel) and can be placed onto the tooth by syringe. Media was treated with NP928
<b>Research Question/Problem/ Need</b>	How can tideglusib be improved to become more water soluble and thus easily applicable to the tooth?
<b>Important Figures</b>	<p><b>A</b></p> <p>(i) Thiazolidinones (TDZD) group → NP928 variant (Water soluble, non-ATP competitive GSK-3β inhibitor). Chemical structures show the TDZD core and the NP928 variant with modifications at Lys 209, Tyr 216, and Arg 96.</p> <p>(ii) MA-HA macromer + Eosin Y + di-thiol PEG → MA-HA hydrogel + NP928. The process involves dental light exposure, resulting in a color change when solidified.</p> <p><b>B</b></p> <p>Diagram illustrating the application of the MA-HA hydrogel + NP928 to a tooth. (I) A drill is used to create a cavity in the enamel and dentine, exposing the pulp. (II) The MA-HA hydrogel + NP928 is applied to the cavity. (III) The hydrogel is solidified by dental light exposure, resulting in sealing and drug release &amp; pulp stimulation.</p> <p>Shows how NP928 can be used on the tooth</p>

<b>#Tags</b>	#Planaria #Methodology
<b>Summary of key points + notes (include methodology)</b>	The article describes different protocols for quantifying blastema growth in regenerating freshwater planarians. The methods described in the article discuss the usage of Fiji/ImageJ software to map out the growth of the planaria, using a caliber or other tool with measurements as a “standard” for the software to compare against. The protocols describe a specific plan for how to image the planaria over the course of 2 weeks (Basic Protocol 1), then described the specific steps for quantifying the blastema size (Basic Protocol 2) and calculating the growth rate using a linear curve fitting in a spreadsheet (Basic Protocol 3).
<b>Research Question/Problem/Need</b>	How can the rate of blastema growth in regenerating planarians be quantified to assess the effects of chemicals on stem cell biology and regeneration?
<b>Important Figures</b>	 <p>Explains how the images help measure blastema growth</p>

<b>#Tags</b>	#WntSignalling #Inhibitor #CanonicalWntSignalling
<b>Summary of key points + notes (include methodology)</b>	The article talks about the usage of different inhibitors to knock out specific components in the Wnt signaling pathway, which can help with tumor treatment. The Wnt pathway is often altered in tumors, leading to its activation that promotes tumor growth. Researchers have found many such inhibitors that target specific components of the Wnt pathway. For example, silencing $\beta$ -catenin is effective in inhibiting colorectal cancer growth. However, the tumor quickly resumes after stopping treatment, which suggests that continuous therapy would be needed for such a solution. Other strategies have also been shown to help, like inhibiting the $\beta$ -catenin with TCF and knocking down TCF4. There are still many challenges associated with targeting $\beta$ -catenin and its binding sites though, because of the difficulty of designing small molecules that can specifically inhibit the nuclear form of $\beta$ -catenin.
<b>Research Question/Problem/Need</b>	Can inhibiting the Wnt signaling pathway serve as an effective therapeutic strategy for cancer treatment, and what are the challenges and potential of targeting specific components of this pathway?

<b>Keywords</b>	Dental epithelial stem cells; Tissue engineering; Label-retaining cells; Lineage tracing; Single-cell sequencing
<b>#Tags</b>	#DentalEpithelialStemCells
<b>Summary of key points + notes (include methodology)</b>	The article discusses the regenerative potential of tooth enamel, which is a highly mineralized tissue that makes up the outermost layer of the tooth. This tissue cannot repair itself after caries or trauma damage due to the loss of DESCs and ameloblasts after the tooth erupts. The article explores the identification and regulatory mechanisms of DESCs in mouse incisors, which can grow continuously due to the DESCs present that regenerate enamel-producing ameloblasts. The researchers use methods like label-retaining cells and lineage tracing, showing that DESCs reside in the labial cervical loop, and can regenerate ameloblasts and other dental epithelial lineages.
<b>Research Question/Problem/Need</b>	How do dental epithelial stem cells (DESCs) in mouse incisors contribute to enamel formation, homeostasis, and repair, and what are the regulatory mechanisms underlying their function?

<b>Source type</b>	Journal Article
<b>Keywords</b>	Wnt3A, dentinogenesis, SHED, odontogenesis
<b>#Tags</b>	#Wnt3A #Activator
<b>Summary of key points + notes (include methodology)</b>	The aim of the researchers of this paper was to investigate the effect of Wnt3A on odonto/osteogenic differentiation of SHEDs and reparative dentine formation in a rat model. SHEDs were cultured with various concentrations of Wnt3A (50–200 ng/ml), showing decreased colony formation and increased expression of osteogenic markers (OSX, BMP2, DMP1) along with enhanced mineralization. Wnt3A treatment led to significant dentine / bone volume formation in rat model with pulp exposure, promoting tertiary dentine formation at the defect sites.
<b>Research Question/Problem/Need</b>	What is the effect of Wnt3a on the odonto/osteogenic differentiation of stem cells isolated from human exfoliated deciduous teeth (SHEDs), and how does it influence reparative dentine formation in a rat model?
<b>Important Figures</b>	 <p><b>BMP2</b></p> <p>Relative mRNA expression</p> <p>WNT3A (ng/mL)</p> <p>Control 50 100 200</p> <p>FIGURE 8 Wnt3a promoted <i>BMP2</i> expression in stem cell from human exfoliated deciduous teeth (SHEDs). Cells were treated with Wnt3a at concentrations of 50, 100, or 200 ng/ml in a normal growth medium for 7 days. <i>BMP2</i> mRNA expression was determined using real-time qPCR. Bars indicate a significant difference compared with the control (<math>p &lt; .05</math>).</p>

<b>Source type</b>	Journal Article
<b>Keywords</b>	Osteogenic Differentiation, DKK1, Wnt Antagonist
<b>#Tags</b>	#WntSignallingPathway #DKK1 #Differentiation #DentalPulpRegeneration
<b>Summary of key points + notes (include methodology)</b>	The study focused on the usage of miR-335-5p to downregulate DKK1, which is a protein that inhibits the Wnt Signalling pathway and thus induces osteogenic differentiation. This process essentially enhances Wnt signalling, as seen by elevated GSK-3 $\beta$ phosphorylation and increased $\beta$ -catenin transcriptional activity. The researchers used miRNA microarray analysis, luciferase assays, and in situ hybridization and ATP staining to measure their results. It was found that miR-335-5p helps with osteogenic differentiation.
<b>Research Question/Problem/Need</b>	How does miR-335-5p aid in osteogenic differentiation?
