## Literature Search Parameters:

These searches were performed between 8/22/25 and 9/30/25.

List of keywords and databases used during this project.

Database/search engine	Keywords	Summary of search
WPI Gordan Library	cerebellar hypoplasia in cats	Cerebellar hypoplasia is a condition caused by panleukopenia virus that occurs in utero when the mother contracts the virus. This causes the baby to have an underdeveloped cerebellum and results in poor balance and coordination issues.
WPI Gordan Library	smart glove parkinson's disease	Engineers have designed a glove that contain piezoelectric and inertial sensors to evaluate and determine the severity of Parkinson's Disease (PD). Using the MDS-UPDRS-III scale, neurologists can change treatment plans remotely whenever the patient does the MDS-UPDRS-III tests at home.
WPI Gordan Library	learning prediction of alzheimer's disease	Alzheimer's Disease (AD) is a neurodegenerative disorder that is characterized by memory loss and cognitive decline, affecting 1 in 9 people aged 65 and older across the U.S. One study uses machine learning techniques that performs predictive analysis to find key brain regions associated with AD. They do this by using numerical data that is derived by MRI scans.

<b>Source type</b>	Secondary source
<b>Keywords</b>	UK Biobank, imprinting disorders, congenital conditions
<b>#Tags</b>	#biology
<b>Summary of key points + notes (include methodology)</b>	<p>There are many variations of what genes can do once a child is conceived. The child inherits two copies of almost every gene from each parent and are generally either turned off or on. But sometimes, a copy can be turned on and expressed, while the other copy is silenced. This can lead to 'imprinting' disorders, which are a group of congenital conditions caused by genomic imprinting, a process where certain genes are expressed differently based on which parent they inherited that gene from.</p> <p>Researchers studying evolution suggest that this silencing of certain genes is because of a conflict surrounding which parent that gene originated from. For example, the expression of paternal genes encourages the offspring's growth, but only because the mother is providing resources for it. Researching the connection between parent-of-origin variants and human traits is difficult because they would need genomic data from that offspring and their parents, which isn't available most of the time. So, to avoid this issue, a research team in Europe and the United States generated a statistical method to infer the genetic variants of the parent of origin by using accessible genomic data from any relatives. They were able to find parental origin of genes for the 109,000 people whose genomic data was in the UK Biobank and they were able to identify 30 variants that would impact growth and metabolism. The reason I chose to read and summarize this article as part of my brainstorming was because I want to do something towards biology and genetics for the research project.</p>

<b>Research Question/Problem/Need</b>	How can variations of gene expression be controlled to prevent imprinting disorders?
<b>Important Figures</b>	No important figures listed
<b>VOCAB: (w/definition)</b>	UK Biobank – Biobank study in the United Kingdom that stores the de-identified biological/health-related data for half a million people Imprinting disorders – Genetic disorders caused by errors in genomic imprinting, where one gene is silenced and only the other one is expressed Congenital conditions – Conditions present at birth
<b>Cited references to follow up on</b>	No cited references listed.
<b>Follow up Questions</b>	Are there any disadvantages to using a biobank as large as the United Kingdoms? What are the advantages to using that biobank?

## Article #2 Notes: The biology of behavior: scientific and ethical implications

Article notes should be on separate sheets

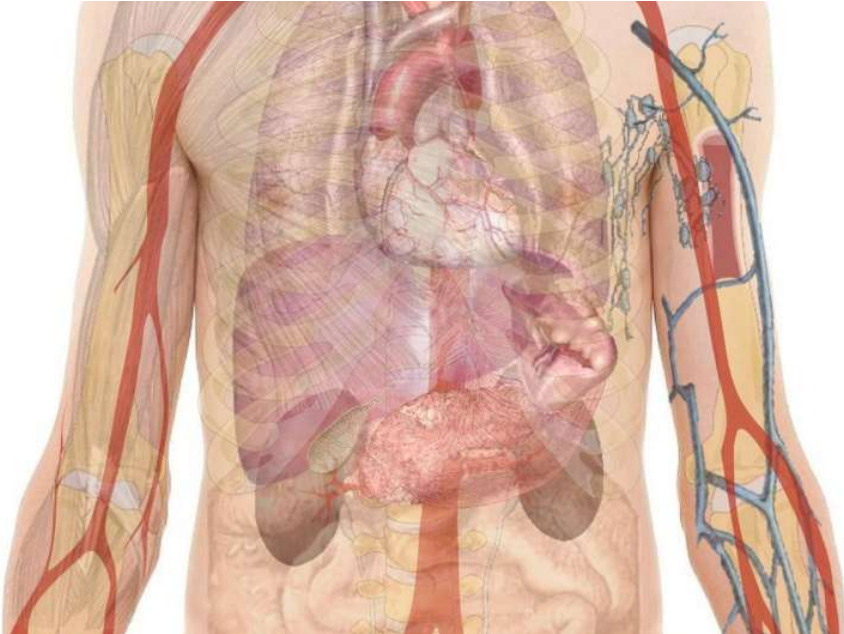

<b>Source Title</b>	The biology of behavior: scientific and ethical implications

<b>Source type</b>	National Library of Medicine article
<b>Keywords</b>	Pleiotropy, epistasis, genome
<b>#Tags</b>	#biology
<b>Summary of key points + notes (include methodology)</b>	<p>The brain is a fascinating organ, mediating our behavioral responses with a brilliant structure and higher cognitive function. These are all embedded within the genome and genes, serving as a complete set of genetic information for an organism. Although behavior is mostly influenced by environment or biographical circumstances, there are forms that are inherited through genes. But the real question was how the brain causes this behavior; the lines of how the genes and/or environmental circumstances affect it. Luckily, the research on behavioral genetics continues to flourish as researchers at the seventh European Molecular Biology Laboratory (EMBL)/European Molecular Biology Organization (EMBO) are developing tools to distinguish the complexity between genes and human behavior. Geneticist Pierre Roubertoux stresses that pleiotropy, the expression of multiple traits by a single gene, epistasis, a phenomenon where one's gene expression affects the expression of another gene, and interactions between the gene and the environment can lead to many different aspects of behavior. This article relates to one of my ideas of how genes and genomes can affect the biology of behavior in the cats in an animal shelter I volunteer at. I wanted to understand the biology of behavior in the human brain before diving into the world of cats as cats and humans have about 90% of the same structure.</p>
<b>Research Question/Problem/Need</b>	If behavior is caused by genetic and/or environmental circumstances, what is the fine line that distinguishes genes and human behavior?

<b>Important Figures</b>	No important figured listed

<b>Source type</b>	Website article
<b>Keywords</b>	Nanomedicine, complement system, iptacopan
<b>#Tags</b>	#nanomedicine
<b>Summary of key points + notes (include methodology)</b>	<p>This article is about an international research study that has recognized promising strategies that can boost the safety of nanomedicines, an advanced therapy that applies nanotechnology and nanoscale materials to diagnose, treat, and prevent diseases. They want to repurpose existing medications approved by the FDA to reduce the damaging immune responses when they react to the nanoparticles. When nanoparticles are introduced to the body during nanomedicine therapy or imaging, it can trigger inflammation in the immune system as the complement system, a group of blood proteins that defend the body against pathogens, accidentally target those friendly and helpful nanoparticles as a potential threat. This could have caused various symptoms including skin rashes, respiratory distress, cardiovascular problems, or dangerous anaphylactic reactions. To address these reactions in the immune system, the research team tested medications that adjusted the immune system to reduce immune attacks without heavily weakening it. They found that iptacopan, a drug used to treat rare blood, nerve, and kidney disorders, was most effective in doing just that. It reduced immune responses but also prevented more serious symptoms from occurring.</p>
<b>Research Question/Problem/Need</b>	How can existing medications be repurposed to reduce the damaging immune responses towards nanoparticles?

<b>Important Figures</b>	 <p>This image was provided on the website article, shows the path of iptacopan could take throughout the body</p>
<b>VOCAB: (w/definition)</b>	<p>FDA – Food and Drug Administration</p> <p>Iptacopan – An oral medication used to treat rare blood disorders, and certain kidney disorders</p> <p>Nanotechnology – Creation, design, and application of nanoparticles to create technology with special properties as it isn't on the same size scale of physical, chemical, and biological properties</p> <p>Nanomedicines – Use of nanotechnology to healthcare to diagnose, treat, and fight off diseases</p>

<b>Source type</b>	Journal article
<b>Keywords</b>	Songbird, blinking, animal communication
<b>#Tags</b>	#animalcommunication #biology
<b>Summary of key points + notes (include methodology)</b>	Environmental noise, otherwise known as noise pollution, can severely impact acoustic communication by affecting key behaviors: predator avoidance, territorial defense, and reproduction. Multimodal signals, signals that send information across sensory channels, can enhance signal detection in noisy environments, allowing animals such as the white-throated dipper to adjust their songs to an ambient environment by also using their blinking rate, a blinking method that compensates for sound masking in loud areas. The field measurements in blinking rate and song volume showed a negative correlation between the two, indicating that these animals can adapt to fluctuating environmental pressures.
<b>Research Question/Problem/Need</b>	How does the white-throated dipper adapt to fluctuating environment pressures?

<p><b>Important Figures</b></p>	<p>This figure shows the relationship between the songbird threshold and the frequency at which they are released at.</p>
<p><b>VOCAB: (w/definition)</b></p>	<p>Song plasticity – The ability for organisms, especially songbirds, to change their songs to adapt to environmental and social interactions.          Multimodal signals – These are specific signals that send information across sensory channels to send a message to another organism</p>
<p><b>Cited references to follow up on</b></p>	<p>Grafe, T. U., &amp; Tony, J. A. <b>Source type</b>	Journal article
<b>Keywords</b>	Cerebellar hypoplasia, panleukopenia virus
<b>#Tags</b>	#cerebellarhypoplasia
<b>Summary of key points + notes (include methodology)</b>	Cerebellar hypoplasia in cats is most commonly caused in utero by a feline panleukopenia virus (parvovirus). It was reported that cerebellar hypoplasia (CH) was not very frequent in dogs and more frequent in cats. To see if the parvoviral DNA was present in dogs and cats with CH, they used PCR on extracted DNA from archival, paraffin-embedded, cerebellar tissue from 8 cats and 10 dogs. They cut the archival brain tissue to look at the microscopic structure and to detect viral proteins. However, to actually detect the parvovirus proteins, they rehydrated the tissue in 70% ethanol and blocked it with 0.5% hydrogen peroxide for 10 minutes at room temperature. Then, they incubated the tissue with rabbit polyclonal anti-CPV antibody for 2 hours at 37 degrees Celsius. After secondary antibodies were applied, they examined the samples via light microscopy. All of the test samples that were animals with cerebellar hypoplasia, parvoviral DNA was present in them.
<b>Research Question/Problem/Need</b>	Can parvoviral DNA be amplified in the feline and canine archival brain tissue of animals with cerebellar hypoplasia?

## Important Figures

This figure shows the PCR amplification for parvoviral DNA, the lower bands represent the

## VOCAB: (w/definition)

Etiology – Etiology are the causes or what causes disease/conditions

Abiotrophy – A condition where there is premature degeneration of the functions in tissues and cells

Archival cerebellar tissue – brain tissue preserved for scientific purposes

## Follow up Questions

Why did the scientists choose to use archival cerebellar tissue instead of fresh, new ones?

## Article #6 Notes: A smart glove to evaluate Parkinson's disease by flexible piezoelectric sensors and inertial sensors

Article notes should be on separate sheets

<b>Source Title</b>	A smart glove to evaluate Parkinson's disease by flexible piezoelectric sensors and inertial sensors
<b>Source citation (APA Format)</b>	De Fazio, R., Del-Valle-Soto, C., Mastronardi, V. M., De Vittorio, M., & Visconti, P. (2025). A smart glove to evaluate parkinson's disease by flexible piezoelectric and inertial sensors. <i>Sensors International</i> , 6, 100324. <a href="https://doi.org/10.1016/j.sintl.2024.100324">https://doi.org/10.1016/j.sintl.2024.100324</a>
<b>Original URL</b>	<a href="https://doi.org/10.1016/j.sintl.2024.100324">https://doi.org/10.1016/j.sintl.2024.100324</a>
<b>Source type</b>	Journal article
<b>Keywords</b>	Parkinson's Disease, piezoelectric sensors, inertial sensors, MDS-UPDRS-III scale
<b>#Tags</b>	#engineering #parkinsonsdisease
<b>Summary of key points + notes (include methodology)</b>	<p>Prior to the presented smart glove, a series of engineers tested different properties of what components could be used in their future model. Combining multiple models, they decided that the new smart glove should have both inertial and piezoelectric sensors and ML algorithms to enhance the efficiency of uploading the data from the MDS-UPDRS-III scale to the cloud database for neurologists so they can adjust treatment plans as needed. There are two piezoelectric sensors within the flexible glove, there is one half-moon shaped sensor at the thumb and index finger in order to pick up all the little signals within the junction. There is also a six-axis inertial sensor in the back of the hand to get data, as having six axis's will allow for the glove to pick up motion in all directions. There is also a PPG sensor at the wrist to measure heart rate and oxygenation levels because PD symptoms can be affected by heart rate and oxygenation levels, and it can exacerbate symptoms or affect movement. Recording heart rate and oxygenation levels allow doctors to determine tremor severity. A microcontroller is also present to read the data from the MDS-UPDRS-III scale and transmit it via Bluetooth through a nRF52840 transceiver so it can get uploaded to the neurologists' cloud databases. Within the glove, there are integrated piezoelectric sensors with flexible TPU filament that have dual-channel conditioning boards used for signal and conditioning so that it</p>

can contain the extra voltages that came from the piezoelectric sensors. Within this board, there is a charge amplifier that boosts output signals, a level shifter, which shifts it to a controlled voltage, and a low-pass filter, which allows the frequency signals to pass through while cutting off higher, larger frequencies.

**Research Question/Problem/Need**

How can we create a smart glove that uses flexible piezoelectric and inertial sensors, and ML algorithms to evaluate the severity and progression of patients with Parkinson’s Disease?

**Important Figures**

This figure shows what the smart glove looks like

<b>Summary of key points + notes (include methodology)</b>	The wobbly cat is another name for a cat with cerebellar hypoplasia. First, this article discusses the three different classifications of ataxia present in cats with CH. There is cerebellar ataxia, vestibular ataxia, and sensory ataxia. Cerebellar ataxia is caused by CH, it is located in the cerebellum, and you can tell if it is cerebellar ataxia if there are head tremors or jerky movements throughout the body. Vestibular ataxia is located in the inner ear or the brainstem, and you can tell if that cat has vestibular ataxia if they continuously tilt their head, fall often, or have nystagmus in their eyes. This can be caused by an ear infection that spreads to the skull, or benign growths that start as young kittens. Sensory ataxia is located in the cervical spine, and some causes of this ataxia is having blunt trauma or deformities in that area. You can tell if a cat has sensory ataxia if they have more motor weakness, a normal head position, or a decrease in limp proprioception.
<b>Research Question/Problem/Need</b>	How can vets determine what type of ataxia a cat with cerebellar hypoplasia has?

<b>#Tags</b>	#parkinsonsdisease
<b>Summary of key points + notes (include methodology)</b>	A new study introduced a new method of geometric algebra-based classification of hand bradykinesia in patients with Parkinson's disease. Current methods of determining the treatment plan tend to only use visuals to assess it and can miss motion changes and introduce variabilities in the data. This study aims to reduce the amount of variety involved and make all data quantitative. This study contained 71 patients, and each performed a test from the MDS-UPDRS-III scale (finger-tapping, rolling hand into fist, and resting tremor). This new smart glove uses a series of electromagnetic sensors to measure the dynamic distances between the fingertips during flexion/extension and adduction/abduction. When analyzing data, they did frequency, range of motion, and asymmetry ratios to receive the amplitude and speed of the hand in motion. For geometric algebra features, this study adopted Clifford geometric algebra and calculated the 3 axis motion trajectories and asymmetrical distances.
<b>Research Question/Problem/Need</b>	How can the new geometric algebra-based classification grow from the current, traditional methods that neurologists use to classify hand

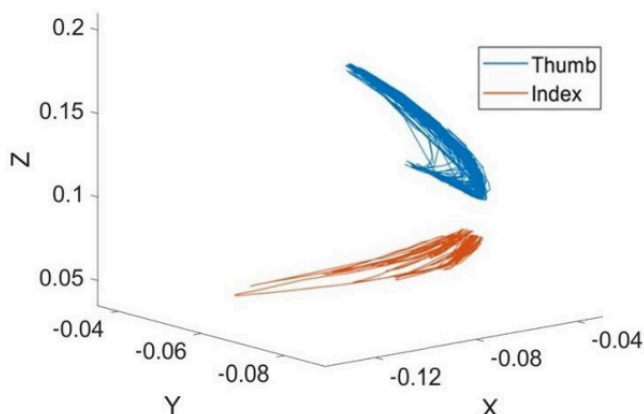

bradykinesia in patients with Parkinson’s disease?

<b>Summary of key points + notes (include methodology)</b>	This study discusses the condition, cerebellar hypoplasia, in two juvenile African grey parrots, instead of more commonly, cats. The scientists in this study were able to determine if these parrots had CH due to common neurological signs: difficulty standing and walking around without assistance and tremors. After seeing these signs, they tested the parrots and found a cerebellar lesion, an injury to the cerebellum. Postmortem, both parrots exhibited a 40-50% reduction of the size of the cerebellum compared to the cerebrum. Histopathology showed that the granular layer was mostly absent, and there was a complete loss of granule cells in the cerebella. The Purkinje cells were highly disorganized and were scattered throughout the superficial cerebella and was also extended into white matter.
<b>Research Question/Problem/</b>	How does the cerebella of the African grey parrot differ from other

<b>#Tags</b>	#engineering #cerebellarhypoplasia
<b>Summary of key points + notes (include methodology)</b>	This article primarily focuses on the advantages to low-cost Arduino boards and how they can be effectively used in software, hardware, and for many psychological and neurophysiological labs. Inside the Arduino, its hardware consists of an open hardware design that mostly come predesigned. There are some several third-party makers that produce shields that allow the Arduino boards to connect wirelessly, and one of the Critical Velocity Shield integrates a 3-axis accelerometer. Arduino hardware uses simplified C++, and Arduino software takes that and compiles it so it can be loaded onto the motherboard. Professional timing hardware can take a lot of money out-of-pocket and can still give small errors when recording data even with an inexpensive Arduino sitting right there. D'Ausilio wanted to prove this and conducted 8 tests that would test the synchronization and accuracy of the Arduino Uno board, and the C++ he coded. He coded with multiple output and logic conditions, but the timing was still stable and great, proving that an inexpensive Arduino can work just as good, or arguably better than professional timing hardware.
<b>Research Question/Problem/Need</b>	Can an inexpensive, low-cost Arduino Uno work just as well or even better than professional timing hardware when in use for psychological and neurophysiological labs?

<b>#Tags</b>	#cerebellarhypoplasia #engineering
<b>Summary of key points + notes (include methodology)</b>	The aim of this study is to characterize the temporal evolution of precision grip movements in patients with cerebellar hypoplasia over 2 years. A 42-year-old adult male participant (LS) was the participant in this study. He has cerebellar hypoplasia and was presented with headache, gait disturbances, visual difficulties, and left dysmetria. He and a control group of 10 healthy male participants of similar age performed a RtG task with their dominant hand towards a thin cylinder. The purpose of this task was to try and prevent the object from falling. They used motion capture with 6-camera SMART-D 3D system, and the markers were placed on the wrist, thumb, and index finger. MRI analysis was also involved to provide imaging of the underdeveloped cerebellum before and after these exercises. Ultimately, these series were able to result that LS exhibited slower RtG movements, which aligns with classic motor markers of congenital cerebellar hypoplasia. Although there was some adaptation from the practice from the test, the smoothness of the movements and control were still impaired.
<b>Research Question/Problem / Need</b>	How does cerebellar hypoplasia affect reach-to-grasp movements? Can reach-to-grasp movements show the motor markers present in patients with cerebellar hypoplasia?

<b>#Tags</b>	#engineering
<b>Summary of key points + notes (include methodology)</b>	<p>The research involved two users running indoors on a treadmill at 16 degrees Celsius to ensure temperature consistency. The participants started at 8 o'clock in the morning and needed to run 21 kilometers while wearing either compression pants or normal shorts. Everyone used their personal running shoes, and they received a break of one week in between the two trials.</p> <p>Those who were wearing the compression pants covered the ankles up to their waists. They were also given normal running shorts as a control variable that exerted no pressure. The participants perceived exertions (RPE) were measured using the Borg 6-20 scale. Hip extension proprioception was evaluated using AMEDA which comprises of three components: a standing platform, horizontal bar position, and a moveable disc. They were instructed to face forward and extend their hip from initial position until their Archilles tendon reverted to its initial position. This test was conducted for both groups in compression pants and normal shorts, and tests showed that in normal shorts, hip proprioception dropped after running 14 km while the proprioception in compression pants held equivalent to the baseline. This shows that compression pants may help maintain hip proprioception during runs up to 14 km.</p>

<p><b>Research Question/Problem/Need</b></p>	<p>Can compression pants improve hip proprioception in half-marathon runners?</p>

<b>#Tags</b>	#engineering
<b>Summary of key points + notes (include methodology)</b>	<p>This study was conducted to determine the effectiveness of the robots' control systems and highlight the robots' application potential. They developed two types of self-balancing robots: one is a conventional, small-sized wheel-legged robot, while the other is a larger self-balancing robot capable of carrying a person. These robots would use a LQR controller to maintain balance and a PD controller to track rotational speed. For the smaller wheel-legged robot, there would only be a leg controller to address rough terrain and jumps while the one capable of carrying a person had a torque sensor to provide real-time mass and CoM. The wheel-legged robot was controlled by an embedded microcontroller, and it showed that it was able to have stable velocity trackings and had successful jump maneuvers. The human-carrying wheelchair also showed stable velocity tracking's with a human on it and was able to climb a 5 cm step. Carefully watching the changes in mass and CoM allow for the microcontroller to perform reliably and shows that LQR and PD's can handle the functions for both robots.</p>

<b>Research Question/Problem/ Need</b>	Can one unified control system keep different types of self-balancing robots stable and safe?

<b>Source type</b>	Journal article
<b>Keywords</b>	Self-balancing robot, control moment gyroscope, disturbance observer, KUWAY
<b>#Tags</b>	#engineering
<b>Summary of key points + notes (include methodology)</b>	<p>Wheeled mobile robots hold a significant advantage over humanoid robots. They are faster so they are able to have greater mobility, better rotation, and speed due to a balance controller that is embedded in the majority of self-balancing robots. Due to this, they have increased popularity as the Segway and the Ninebot, scooter-like self-balancing robots, are major successes across the market. However, increased use also increases probability of injury or death. The balance controller's knowledge of when to generate counter-torque is solely determined by feedback. This causes the controller to be unable to generate counter-torque in a quick enough time, resulting in vast fluctuations in angular tilt and velocity to stabilize itself, increasing the chance of injury to other objects and potential user on the robot. Therefore, the CMG was developed to be integrated into systems like this.</p> <p>The KUWAY, the self-balancing robot presented in this article, consisted of sensors, microcontroller, and a CMG subsystem. The IMU, gyro sensor, and rotary encoder measures tilt angle, angular velocity, and rotational motion. The microcontroller takes this data into account and decides how much corrective action should be taken to give to the CMG subsystem. The CMG itself is made up of DC motors, flywheels, a gimbal stabilizer, and a PID controller. The DC motors generate rotational motion and convert it into kinetic energy. The flywheels take that kinetic energy and continuously spin in order to store the energy in the form of angular momentum. The gimbal stabilizer takes that</p>

momentum to stay charged to constantly tilt the box the CMG is stored in to generate counter torque perpendicular to the disturbance force. To test the KUWAY, a 10 kg weight was dropped from a 25 Degree angle to test the disturbance force with and without a CMG. The figures presented below showcase the results, and the CMG was most effective in stabilizing the robot when presented with a disturbance force.

**Research Question/Problem / Need**

How can a control movement gyroscope (CMG) achieve better mobility and rotation in a self-balancing robot to lower safety and stability risks?

**Important Figures**

Figure 1: without the CMG

Figure 2: with the CMG

Figure 3: comparison of CMG and no CMG

**VOCAB:  
(w/definition)**

Disturbance force – A kick to the robot, a rock thrown, any force that hits the robot  
 Flywheel – A flywheel takes mechanical energy to power itself to spin and store energy  
 Flywheel DC motor – Generates rotational motion as the robot moves  
 Gimbal stabilizer – takes the energy from the flywheel and stores it in the form of angular momentum, producing countertorque where needed  
 PID controller – acts as a checker, smooths any unwanted overcorrection

<b>#Tags</b>	#engineering
<b>Summary of key points + notes (include methodology)</b>	<p>Two-wheeled self-balancing robotic systems (TWSBRs) are slowly beginning to substitute humans in hazardous and challenging environments because they are able to effectively complete difficult missions without having to worry about safety concerns. In the late 1980s, Professor Kazuo Yamato proposed the concept of a TWSBR, as seen in Figure 1a. He designed a two-wheeled balance as opposed to a multi-wheeled mobile robot because the TWSBR holds many advantages that allows them to hold dynamic balance continuously, complete all tasks while taking up minimal space, and recent studies show their rapid development in transportation, entertainment, and service sectors. In these applications, signal processing techniques such as observers, differentiators, and filters play a crucial role in keeping the robot stable. Because in real-time, these techniques are what is constantly updating the robot by sending messages of the current angular velocity and filtering the signal noise of the sensors, ensuring stable and precise control. However, in order for these techniques to be effective, there needs to be extensive consideration of the robot's dynamics, sensor performance, and control algorithms to meet the expectations of the system. Jmel et al. proposed an adaptive observer-based output feedback control method, that primarily focused on estimating the state and weight of the robot, while still being complemented by a PID controller in order to generate the precise control signals needed to keep the TWSBR stable.</p>

<b>Research Question/Problem/Need</b>	What control strategies can be applied to TWSEBRs to optimize their ability to complete difficult tasks while still remaining in balance?
<b>Important Figures</b>	 <p>(a) The concept.</p> <p>Figure 1a.</p>

<b>#Tags</b>	#engineering
<b>Summary of key points + notes (include methodology)</b>	The brushless DC motor (BLDC) is a synchronous electric motor that looks very similarly to a regular DC motor. They both have a linear relationship between voltage, electric current, torque, and revolution per minute (used for rotational speed). However, the brushless DC motor has an electronically controlled commutation system instead of a mechanical commutation, which is more common in brushed motors. The BLDC is most useful in aerospace applications as the ratio of the delivered torque to the size of the motor is higher, which causes noiseless operation, higher speed ranges, and longer operation life. Their control can be managed through sensorless or sensor mode, but to reduce the costs of actuating devices, sensorless control mode is primarily used. All electrical motors that do not require electrical connections are considered brushless permanent magnet machines (PM motors). Because of the power density, reliability, efficiency, maintenance free nature and silent operation, PM motors have been vastly used for industrial automation, computers, aerospace engineering, military, and household products.
<b>Research Question/Problem/Need</b>	What are methods to effectively open the way for full penetration of PM motors into all low cost, high reliability, and large volume applications?

<b>#Tags</b>	#engineering
<b>Summary of key points + notes (include methodology)</b>	<p>The control of a two-wheeled robot is a topic that many people find fascinating due to its large impacts on society. People have been studying this to find the perfect math model and structure characteristics in a helper robot. A PID (Proportional-Integral-Derivative) controller is one of the most commonly used control systems because it's not necessary to know their model equations. Most robots have this controller to mitigate the unstable effects of those without one as it considers the error given and compares it to past experiences to adjust accordingly. The Bimbo robot is a lego-based robot that has precise geometry and robustness. It contains an MPU6050, Kalman filter, various motors that control different variables, a PID controller, an Arduino, and several encoders. After these electronics were integrated into the robot, multiple trials were run on Matlab, creating an algorithm to show the variations on time/signal graphs. One of the more important components in this Bimbo is the Kalman filter. It is used for state estimation to determine and adjust the quality of the sensor measurements from the MPU6050 and IMU to fix the angle of the robot more accurately. It allows enough counter torque to be produced without giving the robot too much overcorrection. It ensures careful adjustment using the PID controller and the Kalman filter.</p>
<b>Research Question/Problem/Need</b>	What could support the PID controller in maintaining a stable environment for self-balancing robots?

<b>Important Figures</b>	 <p>Fully assembled Bimbo Robot</p>

<b>Original URL</b>	<a href="https://pmc.ncbi.nlm.nih.gov/articles/PMC11186075/">https://pmc.ncbi.nlm.nih.gov/articles/PMC11186075/</a>
<b>Source type</b>	Journal article
<b>Keywords</b>	Purkinje cells, Cerebellar cortical degeneration, Genetic, MRI, Inherited
<b>#Tags</b>	#biology #cerebellarhypoplasia
<b>Summary of key points + notes (include methodology)</b>	<p>Inherited neurological diseases are relatively rare in domestic animals, particularly cats. However, cerebellar hypoplasia is one of the most common neurological conditions that is caused when the mother cat is infected with a panleukopenia virus (parvovirus) when the kittens are in utero. But other than cerebellar hypoplasia, infectious disease such as toxoplasmosis and feline infectious peritonitis are less rare, but the chance of remaining meningoencephalitis turning into cerebellar cortical degeneration becomes larger. Cerebellar cortical degeneration is one of the most common neurodegenerative diseases present in domestic animals. In this study, there are multiple cases of domestic animals that have infectious diseases that developed into cerebellar degeneration including two male and one female shorthair cat. Case 1 was the female cat, she had cerebellar ataxia across all of her limbs, and her nystagmus was less severe on the left side of her body. Case 2 was the male cat, and his hopping reactions were delayed with exaggerated responses. Case 3 is the other male cat, a cat with cerebellar degeneration who had a consistent decline for his health.</p> <p>Although the severity of the diseases was different across all animals, their mental status was appropriate, their gait was hypermetric, and intention tremors were heavily present. Some of the highlights throughout cases was that for the first case, it was already suspected that the cat had cerebellar cortical degeneration. Also, the MRI and pathology observations across all three cases are grouped for future sections.</p>

<b>Research Question/Problem/Need</b>	What are the normal and clear signs of cerebellar cortical degeneration in cats based on the three cases conducted on these cats?
<b>Important Figures</b>	 <p data-bbox="522 800 1068 831">Photo of the measurements from the MRI</p>

<b>Follow up Questions</b>	Why did the pathologists necessarily need the histopathology in order to diagnose cerebellar cortical degeneration when there are other ways of determining it?

## Article #19 Notes: Lending a Hand for Parkinson's: Reducing Tremors with a Glove

<b>Source Title</b>	Lending a Hand for Parkinson's: Reducing Tremors with a Glove
<b>Source citation (APA Format)</b>	Kaul, A. (2020). Lending a Hand for Parkinson's: Reducing Tremors with a Glove. <i>Massachusetts Academy of Math and Science at Worcester Polytechnic Institute</i> .
<b>Original URL</b>	Source given by Dr. Crowthers.
<b>Source type</b>	Literature Review
<b>Keywords</b>	Parkinson's Disease, assistive device, tremor frequencies, glove, neurodegenerative disease, Arduino,
<b>#Tags</b>	#engineering
<b>Summary of key points + notes (include methodology)</b>	<p>Parkinson's Disease is a neurodegenerative disease that degrades motor function over time and can decrease a patient's quality of life. One symptom that decreases that quality of life is the number of tremors patients experience on their day-to-day life. Therefore, engineer Anaya Kaul chose to design an assistive glove that could prevent this using an Arduino Uno, gyro-accelerometer, and a gyro-device. A sensor circuit was constructed using an Adafruit 9-DOF Accel/Mag/Gyro+Temp Breakout Board-LSM9DS1 that is compatible with an Arduino UNO board. This sensor can detect tilt, temperature, and changes in rotational motion. It was hooked up to a laptop where four wires were soldered onto the breadboard to keep the pins and wires in place while the application was running. A battery pack was also used and connected to an ESC which tells the hard drive to constantly spin which is consisted of a disk and a brushless motor. The hard drive is covered with an old metal cover and attached with two screws to prevent the disk from touching the user's skin.</p> <p>Data collection from the sensor circuit before and after the activation of the gyro device shows a 67% difference of tremor frequencies. Before wearing the glove, these frequencies averaged around 30.9 tremors for an interval of 20 seconds. After wearing the glove, tremors were able to reduce to 10.1 tremors for an interval of 20 seconds, showing that this assistive device was effective in combating the tremor symptoms present in Parkinson's Disease.</p>

<b>Research Question/Problem/Need</b>	How can an assistive device be designed to help mitigate the tremors present in Parkinson's Disease while still maintaining low-costs?
<b>Important Figures</b>	<p style="text-align: center;">Figure 1</p>  <p style="text-align: center;">Time (Deciseconds)</p> <p>Figure 1: Degrees per second (DPS) vs. Time (deciseconds - 1/10 of a second) before Glove Wearing</p> <p style="text-align: center;">Figure 2</p>  <p style="text-align: center;">Time (Deciseconds)</p> <p>Figure 2: Degrees per second (DPS) vs. Time (deciseconds - 1/10 of a second) during Glove Wearing</p>

<b>Source type</b>	Journal article
<b>Keywords</b>	Nonlinear dynamics, two-wheeled robots, self-balancing robots, control strategies, stabilization control, feedback control, feedback loops
<b>#Tags</b>	#engineering
<b>Summary of key points + notes (include methodology)</b>	<p>Two-wheeled robots hold significant advantages over other mobile robots. Their wheel configuration makes it easier for them to turn on the spot, rotate quicker, and carry out smaller tasks more efficiently. When a robot turns, there are two points for the yaw angle. If you ignore the change of inertia in the yaw axis, it can simplify derivation as the tilt angle changes. A black-box model of system dynamics can be found, too. It allows for model coefficients to be solved through least-square algorithms that solves to independent white noise. To track a certain speed or trajectory, wheel encoders, IMUs, and a Kalman filter is used to estimate the tilt of the robot in the case that the IMU isn't properly working to perform as that accelerometer needed to provide information to the rest of the body.</p> <p>This article also explores a bit into those self-stabilizing robots that have more than two wheels. Because of the weight and increased stability necessary to maintain balance, a suspension system is needed. A suspension system is a network of springs, shock absorbers, linkages, and tires that connect the body of the robot to its wheels.</p>
<b>Research Question/Problem/Need</b>	What control methods have been modelled and developed to take more precise control of a two-wheeled self-stabilizing robot?

<b>Important Figures</b>	 <p data-bbox="521 554 889 583">Figure: Two-Wheeled Robot</p>

<b>Source type</b>	Patent
<b>Keywords</b>	Harness, adjustable straps, chest panel, girth panel, leg openings
<b>#Tags</b>	#engineering
<b>Summary of key points + notes (include methodology)</b>	<p>This patent is an animal harness made for dogs, cats, and other domestic animals. It includes:</p> <ul style="list-style-type: none"> <li>• Loop of webbing <ul style="list-style-type: none"> <li>○ Goes through the animal's neck, shoulders, back</li> <li>○ The webbing is comprised of any suitable material, such as nylon or the like.</li> </ul> </li> <li>• Pouch and the pulsating device <ul style="list-style-type: none"> <li>○ Pulsated Device: this device simulates a heartbeat in a way that the pulsations transmitted are very near the heart of the animal it is on</li> <li>○ The pouch is in direct contact with the chest of the animal and is fixed to the torso belting</li> </ul> </li> <li>• Buckle seatbelt latch <ul style="list-style-type: none"> <li>○ The harness also has a leash that can be converted for different uses, such as seatbelts for travelling</li> <li>○ This latch allows for safe travel and decreases the likelihood of injury if there is a sudden drop</li> </ul> </li> </ul>
<b>Research Question/Problem/Need</b>	How can a pulsating device affect an animal's stress or safety in its everyday life while still securing the animal?

<p><b>Important Figures</b></p>	 <p>FIG. 1 is a plan view of a harness in accordance with the present invention;</p>
<p><b>VOCAB: (w/definition)</b></p>	<p>Vocab listed above in the summary section.</p>
<p><b>Cited references to follow up on</b></p>	<p>N/A</p>
<p><b>Follow up Questions</b></p>	<p>Does the pulsating device have any special effects such as reducing anxiety in domestic animals versus regular harnesses? If so, is it a substantial decrease?</p>

## Patent #2 Notes: Robot self-adaptive impedance control system based on dynamic model

<b>Source Title</b>	Robot self-adaptive impedance control system based on dynamic model
<b>Source citation (APA Format)</b>	Ying, Z., Xuejun, Z., Bo, L., & Guoqiang, L. (2020, September 18). <i>CN110065070B - robot self-adaptive impedance control system based on dynamic model</i> . <b>Source type</b>	Patent
<b>Keywords</b>	Robot, dynamic model, adaptive control, feedback loop
<b>#Tags</b>	#engineering
<b>Summary of key points + notes (include methodology)</b>	<p>This patent primarily wants to solve the issue that industrial robots should be more precise, flexible, and safe because they work with humans everyday. They struggle with unexpected external environmental changes, overcorrection, and maintaining accuracy when handling delicate jobs for humans. This control system uses dynamic modelling to predict how the robot will move while the adaptive impedance controller adjusts the behavior of the robot so it can respond to any form of force quickly.</p> <p>Impedance controller:</p> <ul style="list-style-type: none"> <li>• Ensures the robot moves with more fluidity, reducing the margin of error and chance of injury</li> </ul> <p>Adaptive control strategy:</p> <ul style="list-style-type: none"> <li>• Monitors the position, velocity, and force to make quick changes depending on what conditions it is met with</li> <li>• Reduces the need for extra sensors to carry more work because it's adaptive, so it constantly is looping through a feedback loop to improve it's sense of position and direction</li> </ul>
<b>Research Question/Problem/Need</b>	How can adaptive impedance control help these robots to move more safely and smoothly?

<p><b>Important Figures</b></p>	<p>The diagram illustrates a control system for a robot with force feedback and feedforward. It is divided into three main sections:</p> <ul style="list-style-type: none"> <li><b>位置 and速度控制 (Position and Velocity Control):</b> This section takes the desired position <math>q_d</math> and processes it through a transfer function <math>T</math> to produce <math>x_d</math>. This signal is then compared with the current position <math>x</math> to generate a position error. This error is processed by a proportional gain <math>K_p</math> to produce a desired velocity <math>\dot{x}_d</math>. The desired velocity is compared with the current velocity <math>\dot{x}</math> to generate a velocity error, which is processed by a derivative gain <math>K_d</math> to produce a desired acceleration <math>\ddot{x}_d</math>.</li> <li><b>预测力矩前馈 (Predicted Torque Feedforward):</b> This section takes the desired acceleration <math>\ddot{q}_d</math> and processes it through a transfer function <math>\hat{M}(q)</math>. It also takes the current velocity <math>\dot{q}_d</math> and processes it through a transfer function <math>\hat{C}(q, \dot{q})</math>. The outputs of these two blocks are summed and then multiplied by the Jacobian <math>J</math> to produce a feedforward torque <math>\hat{\tau}</math>.</li> <li><b>接触力矩反馈 (Contact Torque Feedback):</b> This section takes the contact force <math>F</math> and processes it through a Jacobian <math>J^T</math> to produce a contact torque <math>\tau_c</math>. This torque is then compared with the desired torque <math>\tau</math> to produce a torque error, which is processed by a gain <math>K_v</math> to produce a velocity error <math>\dot{\tau}</math>. This velocity error is then processed by a Jacobian <math>J^T</math> to produce a contact force <math>F_c</math>, which is added to the contact force <math>F</math> to produce the final contact force <math>F_c + F</math>.</li> </ul> <p>The final torque <math>\tau</math> is applied to the robot, which outputs the current position <math>q</math> and velocity <math>\dot{q}</math>. The current position <math>q</math> is also used to calculate the Jacobian <math>J</math> and the contact Jacobian <math>J^T</math>.</p>
<p><b>VOCAB: (w/definition)</b></p>	<p>Vocabulary listed above in the summary section.</p>
<p><b>Cited references to follow up on</b></p>	<p>N/A</p>
<p><b>Follow up Questions</b></p>	<p>Quantitatively, how much can the robot improve its performance when adjusting the force response in real time?</p>
