<b>Summary of key points + notes (include methodology)</b>	The study evaluates 21 participants wearing a tactile device and how they rated a sequence of audio stimuli (a few simple melodies). Researchers studied the correspondence between the device's tactile stimuli and the auditory stimuli. Results showed that timing and intensity of the tactile stimuli were strong suggestions of musical enhancement.
<b>Research Question/Problem/Need</b>	<p>How do individual differences (like musical backgrounds, tactile sensitivity, etc.) affect the participant's response to exposure of different audio-tactile stimuli?</p> <p>What impact would varying auditory stimuli have on the detected effectiveness of tactile stimuli?</p> <p>Different genres of music, complexity, tempo, etc.</p> <p>Can long-term exposure to audio-tactile stimuli give way to seeing new types of predictors for tactile musical enhancers?</p>

## VOCAB: (w/definition)

- Neurofeedback: A technique that provides real-time feedback of brain activity (e.g. via EEG) to enable self-regulation of neural states.
- Ambient Intelligence: Environments embedded with sensors, computing, and responsiveness to human presence and context.
- Humanized Computing: Design of systems that adapt to human behaviors, preferences, or emotions.
- Electroencephalography (EEG): Recording of electrical brain activity via electrodes on the scalp.
- Band Power: The magnitude of EEG signal energy within a specific frequency band (e.g. alpha, beta).
- Brain-Computer Interface (BCI): System enabling direct communication or control using brain activity signals.
- Real-Time Feedback: Instantaneous feedback delivered to users based on their brain signals, used in training or adaptation.
- Adaptive Algorithm: A method that adjusts its behavior or parameters based on input data or changing conditions.
- Signal Processing: Techniques to filter, transform, and analyze raw neural signals to extract meaningful metrics.
- Machine Learning Model: An algorithm that learns patterns from data to make predictions or decisions.
- Feature Extraction: The process of selecting or computing relevant metrics (e.g. band powers, connectivity) from raw brain signals.

- User-Centered Design: Designing systems with a focus on usability, user experience, and human needs.
- Latency / Delay: The time lag between recording neural activity and producing feedback or system response.
- Artifact Rejection / Correction: Techniques to remove noise (blinks, muscle movement) from EEG data.
- Cognitive Load / Cognitive Demand: The mental effort required to perform a task, often reflected in EEG changes.
- Personalization / Individualization: Tailoring system settings or protocols (e.g. target frequency bands) to each user.

## Article #2 Notes: Modelling of Musical Perception using Spectral Knowledge Representation

<b>Source Title</b>	Modelling of Musical Perception using Spectral Knowledge Representation
<b>Source citation (APA Format)</b>	Homer, S. T., Harley, N., & Wiggins, G. A. (2024). Modelling of Musical Perception using Spectral Knowledge Representation. <i>Journal of Cognition</i> , 7(1). <a href="https://doi.org/10.5334/joc.356">https://doi.org/10.5334/joc.356</a>
<b>Original URL</b>	<a href="https://journalofcognition.org/articles/10.5334/joc.356">https://journalofcognition.org/articles/10.5334/joc.356</a>
<b>Source type</b>	Scientific publication
<b>Keywords</b>	Music perception, spectral analysis, key affinity, key distance, resonance, cognitive modelling, knowledge representation, Hilbert space, neural dynamics
<b>#Tags</b>	
<b>Summary of key points + notes (include methodology)</b>	The article introduces spectral knowledge representation, a novel approach for AI and cognitive modeling focused on the brain's oscillatory behavior. It says that resonances, which are literal representations of waves, describe the dynamics of neural assemblies processing perceived input. Resonances are mathematical structures like damped oscillators, suitable for modeling neural dynamics because they naturally arise from linearized dynamical systems near a stationary point, offering a physiologically plausible primitive. When applied to music perception, this model captures pitch and chord/key distances, aligning with empirical data from Krumhansl and Kessler. This model proposes that there is an underlying mechanism for music perception, which unifies key and chord differences and offers a computationally less demanding alternative to other dynamical models. This mechanism can also help form the base representation for the broader Information Dynamics of Thinking cognitive architecture.
<b>Research Question/Problem/ Need</b>	The need is to find a more biologically-inspired or neurally plausible way to represent perceptual and cognitive knowledge, especially in the domain of music perception.

## Important Figures

## VOCAB: (w/definition)

- Spectral Knowledge Representation: A modeling approach that uses literal wave / oscillatory representations to encode perceptual and cognitive information.
- Oscillatory Neural Assemblies: Groups of neurons that produce rhythmic (wave-like) electrical activity, often associated with representing sensory or cognitive content.
- Harmonic Distance: A measure of how “far apart” two pitches, chords, or keys are in musical space (often in perceived similarity).
- Key Affinity / Key Distance: The perceived closeness or distance between musical keys (tonal centers).
- Resonance: The phenomenon by which neural assemblies oscillate more strongly in response to input frequencies that match or harmonize with their natural (preferred) frequencies.
- Hilbert Space: A mathematical space used in signal analysis and wave functions; essentially a vector space where waveforms can be represented and manipulated.
- Toroidal Model: A geometric/topological model (a torus-like structure) that represents musical pitch and key relationships in a continuous, curved space.
- Neural Dynamics: How the activity of neural populations evolves over time, especially with respect to oscillations, interactions, and transitions.
- Cognitive Architecture: A theoretical model of how cognitive processes are organized, including how perception, prediction, memory, and representation interact.
- Information Dynamics of Thinking (IDyOT): The larger framework within which spectral knowledge representation sits, proposing cognitive operations like segmentation, categorization, prediction, and abstraction.

<b>Source type</b>	Scientific journal
<b>Keywords</b>	Consonance, biology, music, audition, vocalization
<b>#Tags</b>	
<b>Summary of key points + notes (include methodology)</b>	The article examines musical consonance, considering mathematical, physical, and biological interpretations, and concludes that a biological rationale provides the most reasonable explanation. Consonance has been attributed to the mathematical simplicity of small integer ratios, though this theory struggled to explain why simplicity is pleasing. The scientific revolution shifted focus to physical explanations, most notably Hermann von Helmholtz's roughness theory, which proposed that consonance comes from the absence of "jarring" amplitude fluctuations caused by sound wave interference. The article also discusses an evolved attraction to the harmonic series that characterizes human vocalizations, arguing that our auditory system is uniquely tuned to process these biologically important social sound signals with special efficiency. This perspective suggests that the more voice-like a tone combination is, the more appealing it becomes, with research showing that popular musical intervals are statistically emphasized in vocal spectra and that preferred scales conform to uniform harmonic series. This biological framework relates to the topic of modeling musical perception by moving the focus from abstract mathematical principles or purely physical interactions to the evolutionary and biological aspects of human auditory processing.
<b>Research Question/Problem/ Need</b>	Why do certain combinations of tones sound pleasant, while others don't?

## Article #4 Notes: Neuroscientists explore the intersection of music and memory

<b>Source Title</b>	Neuroscientists explore the intersection of music and memory
<b>Source citation (APA Format)</b>	Georgia Institute of Technology. (2024). Neuroscientists explore the intersection of music and memory. <i>ScienceDaily</i> . <a href="https://www.sciencedaily.com/releases/2024/08/240828224256.htm">https://www.sciencedaily.com/releases/2024/08/240828224256.htm</a>
<b>Original URL</b>	<a href="https://research.gatech.edu/feature/music-and-memory">https://research.gatech.edu/feature/music-and-memory</a>
<b>Source type</b>	Journal article
<b>Keywords</b>	Music, episodic memory, memory recollection, false memory, emotion, fMRI, amygdala
<b>#Tags</b>	
<b>Summary of key points + notes (include methodology)</b>	Neuroscientists at Georgia Institute of Technology led by Yiren Ren, a Ph.D. student, are exploring the significant intersection of music and memory, suggesting possible therapeutic applications for mental health. Their research, explained in two papers, looks at how music impacts both the formation of new memories and the emotional quality of existing ones. One study showed that familiar, more predictable music can increase concentration and learning by helping the brain make a framework for new information, while unfamiliar or irregular music can cause disruption. The second study discussed that music with stronger emotional notes can change the quality of existing memories, including ones connected with difficult experiences. In the study, participants who were reminded of tough memories while listening to film soundtracks added new emotions that matched the music, and this addition seemed long-lasting. This research indicates the flexibility of memory in response to music

	and that it has the ability to help individuals shift emotional tones attached to certain memories.
<b>Research Question/Problem/Need</b>	How does music influence learning and memory?
<b>VOCAB: (w/definition)</b>	<ul style="list-style-type: none"> <li>• Encoding: The process of forming a new memory (learning) by transforming sensory input into a storable neural code.</li> <li>• Recollection / Recall: The act of retrieving previously stored memories.</li> <li>• Affective / Emotional Tone: The emotional quality (positive, negative, neutral) associated with a memory.</li> <li>• Music Schema / Musical Structure: The organized, predictable patterns in melody, harmony, rhythm, which listeners internalize (schemas).</li> <li>• Familiar Music: Music known previously by the listener (melodies, rhythms) that aligns with their musical expectations.</li> <li>• Irregular / Atonal Music: Music that violates typical structure, melody, or harmonic expectations (less predictable).</li> <li>• Modulation: In this context, the influence or change induced (e.g. music modifying emotional tone of memory).</li> <li>• Scaffold (cognitive scaffold): Support structure in cognition into which new information can be integrated; here, structured music serving as a scaffold for learning.</li> <li>• fMRI (functional Magnetic Resonance Imaging): Brain imaging method that detects changes in blood flow to infer neural activity.</li> <li>• Amygdala: A brain region crucial in processing emotions, especially fear or negative affect, often implicated in emotional memory.</li> </ul>

<b>Original URL</b>	<a href="https://doi.org/10.1007/s10548-024-01076-w">https://doi.org/10.1007/s10548-024-01076-w</a>
<b>Source type</b>	Journal article
<b>Keywords</b>	Neurofeedback, Audiovisual stimulus, attention, EEG, MAAS, Stroop
<b>#Tags</b>	
<b>Summary of key points + notes (include methodology)</b>	<p>The article investigates whether combining audio and visual feedback in neurofeedback training can more effectively improve attention compared to visual-only feedback. Neurofeedback is a technique that trains individuals to regulate their brain activity using real-time EEG signals, and this study aimed to determine whether adding an auditory component could enhance the process.</p> <p>Researchers divided 21 healthy participants into two groups: one receiving audiovisual feedback (G1) and the other visual-only feedback (G2). Both groups completed six neurofeedback sessions on alternating days. The neurofeedback targeted beta-band activity at the frontocentral EEG site FC5, a region associated with attention and cognitive control. Participants' progress was measured through EEG recordings, behavioural tasks (such as the Stroop test), and self-reported mindfulness scores.</p> <p>Results showed that the audiovisual group demonstrated a significant increase in global beta activity over the training period compared to the visual-only group. Further EEG analysis revealed that this group also exhibited improvements in more detailed neural dynamics: dwell time (how long the brain maintained a high-beta state), fractional occupancy (the</p>

	<p>proportion of time spent in that state), and transition probability (the likelihood of switching into that state) all increased significantly. These findings suggest stronger and more sustained engagement of attentional neural networks in participants who received audiovisual cues.</p> <p>Behaviorally, the audiovisual group outperformed the visual-only group on the Stroop task, showing both higher accuracy and faster reaction times, indicating enhanced attentional control and cognitive processing speed. Additionally, their mindfulness scores (MAAS-15) improved, suggesting that the benefits of training extended to broader aspects of cognitive awareness. The researchers concluded that multisensory (audio-visual) feedback can make neurofeedback training more effective and engaging, potentially leading to faster learning and stronger attention-related outcomes. However, they emphasized that consistent practice over multiple sessions remains essential to achieve lasting neural and behavioural changes. Overall, the study highlights how integrating multiple sensory modalities into neurofeedback may improve both neural efficiency and cognitive performance.</p>
<b>Research Question/Problem/Need</b>	<p>Does combining auditory and visual feedback lead to greater improvements in attention and related brain activity compared to visual feedback alone?</p>
<b>VOCAB: (w/definition)</b>	<ul style="list-style-type: none"> <li>• Neurofeedback (NF): A brain-training technique that provides real-time feedback on brain activity to help individuals learn to regulate it.</li> <li>• Electroencephalography (EEG): A method for recording the brain's electrical activity using sensors placed on the scalp.</li> <li>• Beta Activity / Beta Band: A range of brainwave frequencies (13–30 Hz) associated with focus, alertness, and active thinking.</li> <li>• Frontocentral Region (FC5): A specific EEG electrode site near the front-left area of the head, linked to attention and cognitive control.</li> <li>• Audio-Visual Feedback: Feedback that combines both sound and visual cues to show how well a person is controlling their brain activity.</li> <li>• Visual Feedback: Feedback presented only through visuals, such as graphs, animations, or color changes.</li> <li>• Global Beta Power: The overall level of beta-wave activity across the brain.</li> <li>• EEG State Dynamics: The patterns and timing of how brain activity changes over time.</li> <li>• Dwell Time: The average amount of time the brain stays in a particular EEG state.</li> <li>• Fractional Occupancy: The percentage of total time the brain spends in a specific EEG state.</li> <li>• Transition Probability: The likelihood that the brain will shift from</li> </ul>

one EEG state to another.

- Stroop Task: A psychological test that measures attention and cognitive control by requiring participants to name the color of a word rather than the word itself.
- MAAS-15 (Mindful Attention Awareness Scale): A questionnaire that measures how mindful and aware a person is of the present moment.
- Pilot Study: A small, preliminary version of a study designed to test methods and gather initial results before a larger experiment.
- T-test: A statistical test used to compare the averages of two groups to see if they differ significantly.
- P-value: A measure of statistical significance; values below 0.05 indicate that results are unlikely to be due to chance.

<b>Summary of key points + notes (include methodology)</b>	<p>The article provides a detailed overview of how neurofeedback works, how systems are designed, and where it is applied. Neurofeedback is explained as a noninvasive brain-training method that uses real-time EEG feedback to help individuals learn to control their brain activity. The authors describe different EEG frequency bands—delta, theta, alpha, beta, and gamma—and explain how each is targeted in various training protocols to improve mental states such as focus, relaxation, or creativity. Methodologically, the review outlines how neurofeedback systems are built using electrodes (following the 10–20 EEG placement system), amplifiers, signal processing software, and feedback interfaces that can be visual, auditory, or both. The paper discusses several types of neurofeedback, including frequency/power-based training, slow cortical potentials (SCP), hemoencephalographic feedback (HEG), LORETA-based training, and real-time fMRI neurofeedback, noting that each method targets different neural mechanisms. Clinically, neurofeedback has been used to treat ADHD, anxiety, depression, epilepsy, autism, and insomnia, and has also been applied to performance enhancement in athletes and professionals. However, the authors highlight key challenges: neurofeedback can be time-consuming, costly, and its results vary between individuals. The field also suffers from methodological</p>

	<p>inconsistencies, such as differing electrode placements and feedback designs, which make it difficult to compare results across studies.</p>
<p><b>Research Question/Problem/ Need</b></p>	<p>How are neurofeedback systems designed and applied across clinical and cognitive domains? What methodological factors influence their effectiveness?</p>

<b>Source type</b>	Journal article
<b>Keywords</b>	Neurofeedback; Cognitive performance; Sensorimotor rhythm
<b>#Tags</b>	
<b>Summary of key points + notes (include methodology)</b>	<p>The article examines how different types of neurofeedback (NF) training influence brainwave activity and cognitive performance. The researchers aimed to determine whether training specific EEG frequency bands, particularly the sensorimotor rhythm (SMR; 12–15 Hz), could lead to measurable improvements in attention, reaction time, and executive function. Their findings showed that participants who trained with the SMR protocol successfully increased SMR activity after eight training sessions, demonstrating that neurofeedback can selectively enhance targeted brainwave frequencies. This neural improvement was accompanied by better performance on cognitive tasks, particularly in measures of attention and reaction speed, suggesting a link between SMR regulation and cognitive control.</p> <p>The methodology involved dividing participants into groups, each trained using different neurofeedback protocols. Over eight sessions, participants received real-time EEG feedback to learn how to modulate specific frequency bands. The SMR group focused on increasing power in the 12–15 Hz range, while comparison groups trained other frequency ranges. Cognitive performance was assessed before and after training using standardized reaction-time and attention-based tasks. EEG recordings were analyzed to confirm whether participants had successfully modulated their target brainwave activity. The results indicated that only the SMR-trained group showed both a significant rise in SMR power and corresponding cognitive gains.</p> <p>Overall, the study provides evidence that neurofeedback training can produce frequency-specific changes in brain activity that transfer to improvements in</p>

	<p>certain aspects of cognition. However, the authors note that the relatively short training duration and small sample size limit the generalizability of the findings. They recommend further research with more sessions and larger participant groups to better understand how different neurofeedback protocols affect cognitive performance and neural plasticity.</p>
<p><b>Research Question/Problem/ Need</b></p>	<p>Do different neurofeedback training protocols, particularly those targeting the sensorimotor rhythm (SMR), lead to specific changes in brainwave activity and corresponding improvements in cognitive functioning?</p>

<b>Source type</b>	Journal article
<b>Keywords</b>	Neurofeedback, EEG, upper alpha, trainability, cognitive performance, mental rotation
<b>#Tags</b>	
<b>Summary of key points + notes (include methodology)</b>	The study investigates whether individuals can learn to increase their upper alpha EEG activity through neurofeedback training and whether this change translates into cognitive improvement. The researchers hypothesized that training participants to self-regulate their upper alpha rhythm—an individualized frequency range associated with memory and attention—would enhance performance on mental and memory tasks. Participants underwent several neurofeedback sessions where they received real-time visual feedback of their brain activity and were encouraged to raise their upper alpha power. EEG data were recorded and analyzed to determine whether alpha power increased over time, and participants completed cognitive tests before and after training to assess behavioral effects. Results showed that most participants successfully increased their upper alpha amplitude across sessions, and those who did demonstrated improvements in cognitive performance, particularly in tasks involving mental rotation and short-term memory. The findings suggest that individualized neurofeedback in the upper alpha band can strengthen cognitive function by promoting better self-regulation of brain activity.
<b>Research Question/Problem/Need</b>	Can individuals learn to self-regulate their upper alpha EEG activity through neurofeedback, and does this regulation lead to measurable improvements in cognitive performance?

## Important Figures

## VOCAB: (w/definition)

- Upper Alpha Band: The higher sub-range of the alpha frequency band (often  $\sim 10$ – $12$  Hz or subject-specific), associated with cognitive idling or top-down inhibitory control.
- Spectral Power / Band Power: The magnitude of EEG signal energy in a given frequency band (e.g. upper alpha) over time.
- Artifact Correction / Artifact Rejection: Methods to remove or reduce noise in EEG (e.g. from eye movements, muscle activity) before spectral analysis.
- Baseline EEG / Resting State: EEG measurement taken before any training or manipulation, used to calibrate or compare later changes.
- Transfer Effect: Improvement in cognitive tasks (not directly trained) following neurofeedback training, implying generalization of learned regulation.
- Sham Feedback: A control condition in neurofeedback where the feedback given is not contingent on the subject's actual brain activity (used to control for placebo).
- Within-Subject Design: An experimental design in which the same participants are measured repeatedly (e.g. before, during, after training).
- Correlation / Regression Analysis: Statistical methods to examine whether change in EEG measure (upper alpha power) predicts change in behavioral performance.
- Spectral Analysis / FFT (Fast Fourier Transform): Algorithm to convert time-domain EEG signals into frequency-domain components (used to

	<p>compute band powers).</p> <ul style="list-style-type: none"> <li>• Operant Conditioning: In this context, the learning principle that participants are rewarded (via feedback) when their brain activity moves toward a target (increasing upper alpha).</li> </ul>

<b>Summary of key points + notes (include methodology)</b>	Egner (2004) conducted a study to investigate the effects of neurofeedback training on the low beta frequency band in healthy individuals. Participants underwent EEG biofeedback sessions aimed at increasing their low beta power. The study utilized a within-subject design, where each participant served as their own control, ensuring that observed effects were attributable to neurofeedback intervention. Cognitive performance was assessed using tasks that measure attention and memory. Results indicated that participants who successfully increased their low beta activity showed significant improvements in cognitive performance, suggesting that targeted neurofeedback can modulate brain activity and enhance specific cognitive functions.
<b>Research Question/Problem/Need</b>	Can neurofeedback training targeting the low beta ( $\beta$ 1) frequency band enhance cognitive performance in healthy individuals?

<b>#Tags</b>	
<b>Summary of key points + notes (include methodology)</b>	<p>The study “Double-Blind Single-Session Neurofeedback Training in Upper-Alpha for Cognitive Enhancement of Healthy Subjects” by Escolano et al. (2012) examines whether a single session of upper-alpha neurofeedback training can enhance cognitive performance in healthy individuals. The researchers used a double-blind, sham-controlled design to ensure that any observed effects were due to true neurofeedback rather than placebo influences. Nineteen participants were divided into two groups: one received real-time EEG feedback based on their own upper-alpha (UA) activity—an individualized frequency band linked to attention and working memory—while the control group received sham feedback unrelated to their brain activity. Training occurred over a single 25-minute session, divided into five 5-minute trials, where participants attempted to increase their upper-alpha power at parieto-occipital sites (P3, Pz, P4, O1, O2).</p> <p>Before and after training, participants completed a series of <b>cognitive and psychological tests</b>—including mental rotation, PASAT, RAVLT, Stroop, and TMT—to assess changes in attention, memory, and executive function. The results showed that only the real neurofeedback group achieved a significant <b>increase in upper-alpha power</b> and greater <b>alpha desynchronization</b> during cognitive tasks, suggesting enhanced neural engagement. Behaviorally, this</p>

	<p>group also demonstrated <b>improvements in working memory and mental rotation performance</b>, though not all changes reached statistical significance. These findings indicate that even a single session of individualized upper-alpha neurofeedback can induce measurable neurophysiological changes and modest cognitive benefits. However, the authors note that more robust and lasting effects likely require multiple training sessions and larger participant samples. Overall, the study provides preliminary evidence that upper-alpha neurofeedback can serve as a short-term method for cognitive enhancement in healthy adults.</p>
<b>Research Question/Problem/Need</b>	<p>Can a session of individualized upper-alpha neurofeedback training enhance alpha power and improve cognitive performance in healthy individuals?</p>
<b>Important Figures</b>

- <https://www.sciencedirect.com/science/article/abs/pii/S0149763413001279>

**Follow up Questions**

- How stable are resting alpha predictors over time, and would repeated baseline EEG measurements improve prediction accuracy?
- Would combining baseline alpha power with early-session learning slopes provide a stronger predictor of neurofeedback success than just baseline measures?
- How early in training can reliable predictions be made, and is one session sufficient or are multiple early sessions required?

<b>Source type</b>	Journal Article
<b>Keywords</b>	Alpha reactivity, Inter-individual variability, Leads selection, Peak frequency, Transition frequency, Spectrum
<b>#Tags</b>	
<b>Summary of key points + notes (include methodology)</b>	<ul style="list-style-type: none"> <li>• Uses a method called Channel Reactivity-Based (CRB) to determine individual alpha frequency (IAF).</li> <li>• CRB focuses on task-related alpha activity rather than resting spectral peaks</li> <li>• Compared resting vs. task spectra to identify alpha desynchronization regions <ul style="list-style-type: none"> <li>○</li> </ul> </li> <li>• Computed a reactivity index to quantify the responsiveness of alpha</li> <li>• Calculated Channel Alpha Frequencies (CAFs) and the median was derived as the IAF.</li> </ul>
<b>Research Question/Problem/ Need</b>	How can individual alpha frequency be reliably determined without relying on visible spectral peaks, while capturing task-relevant neural dynamics?
<b>Important Figures</b>	<p style="text-align: center;"><small>A. Goljahani et al. / NeuroImage 60 (2012) 774–786</small></p> <p><b>Fig. 1.</b> Representative cases of resting (red) and test (blue) EEG spectra. Panel (a) illustrates an example of peak frequency (PF) <math>f_p</math> determination by the PF method. In the picture, two vertical dotted black lines delimit the (8, 13) Hz alpha range and the vertical solid line is drawn in correspondence with <math>f_p</math>. Panel (b) shows an example of gravity frequency <math>f_g</math> determined by the extended band (EB) method for a representative test spectrum that is quite flat in the alpha range. In the picture, a vertical solid line is drawn in correspondence with <math>f_g</math> and the interval on which it was computed (the extended alpha band) is delimited by two vertical dotted lines. Panels (c) and (d) show two examples of gravity frequencies <math>f_g</math> determined by the transition frequency (TF) method. The panels depict two representative cases of superimposed resting and test spectra with the relative TFs. For both images, vertical dotted lines delimit the interval from TF to TF + 5 Hz and the vertical solid line is drawn in correspondence with <math>f_g</math>.</p>

**Fig. 2.** Block diagram illustrating the three steps of the CRB method.  $\mathcal{R}_i(f)$  and  $\mathcal{T}_i(f)$  are the resting and test spectrum, respectively, for the  $i$ -th lead;  $f_i = (f_1, f_2)$ , where  $f_1$  and  $f_2$  are the boundaries of the responsiveness interval for the  $i$ -th lead;  $\rho_i$  is the reactivity index relative to  $f_i$ ;  $\mathcal{L}$  is the set of leads selected by the CRB method and  $\hat{f}_\alpha$  is the individual alpha frequency (IAF, determined as the median of the CAFs relative to the leads in  $\mathcal{L}$ ).

**Fig. 3.** Panels (a)–(d): four representative cases of resting EEG spectra (red). Panels (e)–(h): the same as (a)–(d) with superimposed test EEG spectra (blue) and responsiveness regions shaded in grey. The  $\rho$  values were computed using the area of the shaded region [numerator of Eq. (1)] and the frequency interval  $(f_1, f_2)$  [denominator of Eq. (1)].

### VOCAB: (w/definition)

- Alpha reactivity: Reduction, or desynchronization of alpha power during cognitive tasks
- CAF: alpha frequency computed per EEG channel
- Reactivity index: measure of alpha responsiveness (quantitative)
- Peak frequency (PF): frequency of maximum power in alpha band during rest
- Extended band (EB): alpha frequency calculated with a visually defined band (usually from a graph)
- Transition frequency (TF): frequency where theta synchronization shifts into alpha desynchronization

### Cited references to follow up on

### Follow up Questions

- Can CRB improve personalization of NFT frequency targets?
- How stable is CRB-derived IAF over sessions?

## Article #15 Notes: Predicting Successful Learning of SMR Neurofeedback in Healthy Participants: Methodological Considerations

<b>Source Title</b>	Predicting Successful Learning of SMR Neurofeedback in Healthy Participants: Methodological Considerations
<b>Source citation (APA Format)</b>	Weber, E., Köberl, A., Frank, S., & Doppelmayr, M. (2011). Predicting Successful Learning of SMR Neurofeedback in Healthy Participants: Methodological Considerations. <i>Applied Psychophysiology and Biofeedback</i> , 36(1), 37–45. <a href="https://doi.org/10.1007/s10484-010-9142-x">https://doi.org/10.1007/s10484-010-9142-x</a>
<b>Original URL</b>	<a href="https://link.springer.com/article/10.1007/s10484-010-9142-x">https://link.springer.com/article/10.1007/s10484-010-9142-x</a>
<b>Source type</b>	Journal Article
<b>Keywords</b>	Neurofeedback, SMR, predicting performance
<b>#Tags</b>	
<b>Summary of key points + notes (include methodology)</b>	<ul style="list-style-type: none"> <li>• Major challenge in NF research is the high number of training sessions required, and the presence of non-responders.</li> <li>• Focuses on sensorimotor rhythm (SMR, 12-15 Hz) NF in healthy participants</li> <li>• Conducted 25 SMR NF sessions with 13 participants, and 30 sessions with 14 participants</li> <li>• Participants received visual feedback that represented SMR amplitude and instructed to use mental strategies to increase it.</li> <li>• Performers and non-performers were classified based on: <ul style="list-style-type: none"> <li>• <math>\geq 8\%</math> increase in SMR by the end of training</li> <li>• + learning trend across sessions</li> </ul> </li> <li>• Found that performance at TP 11 (11 sessions) could reliably predict final learning outcomes</li> <li>• A formula that subtracted individual variability from amplitude increase correctly classified most participants</li> </ul>
<b>Research Question/Problem/ Need</b>	Can early neurofeedback performance be used to predict whether an individual will successfully learn to modulate SMR EEG activity?

**Important Figures**

**Fig. 1** The graphic in figure represents the feedback display viewed by the participants. The *white circular area* in the middle of the screen, which indicates the amplitude of the SMR (12–15 Hz) frequency band, is surrounded by a *gray “threshold circle”*. The three *bars* on the right-hand side of the screen represent the amplitudes of the three inhibitory bands (3–5, 22–30, and 45–60 Hz). A counter is displayed at the *top* of the screen; every time a participant increased and maintained the size of the *white circle* to an area larger than the threshold circle for more than 250 ms, a point was added to the counter

**Fig. 2** The percent amplitude increase for TP 4–TP 25 for the participants of experiments 1 (*upper panel*) and 2 (*lower panel*). Significant differences between the performers and non-performers, as determined with Mann–Whitney *U* tests, are indicated with one or two asterisks for the 5 or 1% level of significance, respectively

**VOCAB: (w/definition)**

- Sensorimotor rhythm (SMR): EEG frequency band between 12-15 Hz, associated with motor inhibition and attention regulation
- Time period (TP): Median EEG amplitude calculated across 3 consecutive training days

<b>Summary of key points + notes (include methodology)</b>	<ul style="list-style-type: none"> <li>• Investigates whether NFT can manipulate neural synchrony and improve cognition</li> <li>• Compares gamma-band NF vs beta-band NFT</li> <li>• Demonstrates that gamma NFT increases local gamma power and frontal-occipital gamma coherence <ul style="list-style-type: none"> <li>○ Beta NFT primarily increases long-range beta coherence, and not local beta power</li> </ul> </li> <li>• Supports the idea that early neuroal changes during NFT reflect trainability and functional relevance</li> <li>• Conducted double-blind, multisession NFT with randomly assigned gamma and beta groups with 17 healthy adults.</li> <li>• Analyzed EEG power and coherence changes within and across sessions</li> <li>• Compared pre/post behavior</li> </ul>
<b>Research Question/Problem/Need</b>	Does experimentally enhancing neural synchrony in specific frequency bands through neurofeedback causally influence cognitive control and memory processes?

## Important Figures

**Fig. 3.** The neurofeedback training led to an increase of occipital GBA in the GBA+ group compared to the BBA+ group within the last session (first 5 min versus last 5 min) compared with the first session (A). Across sessions (first session versus last session), the neurofeedback training resulted in an increase of occipital (B) and frontal (C) GBA in the GBA+ group compared to the BBA+ group. Error bars represent standard errors, asterisks indicate significance level of  $p < .05$ .

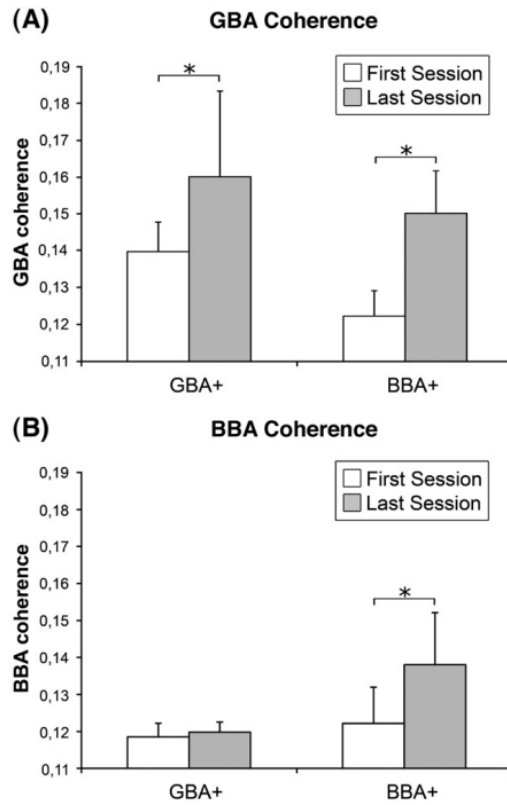

Fig. 4. Across sessions, the neurofeedback training resulted in a significant increase in GBA coherence in both groups (A) and a significant increase of BBA-coherence in the BBA+ group (B). Error bars represent standard errors, asterisks indicate significance level of  $p < .05$ .

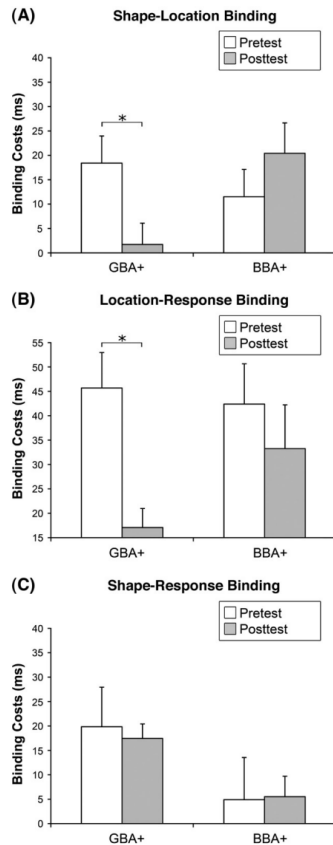

Fig. 5. Reaction time data of the binding task. The neurofeedback training resulted in a decrease of binding costs between shape and location (A) and between location and response (B), but not between shape and response (C). Error bars represent standard errors, asterisk indicates significance level of  $p < .05$ .

#### VOCAB: (w/definition)

- Neural synchrony: Coordinated timing of neural firings across neurons or brain regions
- Gamma-band activity (GBA)
- Coherence: measure of functional connectivity between EEG signals at different brain sites
- Recollection: conscious retrieval of contextual details about a memory
- Cognitive control: ability to regulate attention, memory retrieval, and behavior

<b>Source type</b>	Journal Article
<b>Keywords</b>	Gamma, Neurofeedback, Binding, Feature integration, Intelligence
<b>#Tags</b>	
<b>Summary of key points + notes (include methodology)</b>	<ul style="list-style-type: none"> <li>• Neural synchronization in the gamma frequency band (<math>\approx 30\text{--}60</math> Hz) has been theorized to underlie visual feature binding and fluid intelligence.</li> <li>• Study aimed to provide causal evidence by directly manipulating gamma activity using NFT</li> <li>• Participants were trained over 8 sessions to either increase gamma power (gamma-up group) or suppress gamma power relative to beta power (control group)</li> <li>• Found that participants successfully learned to increase gamma-band power via NF</li> <li>• Increased gamma power led to reduced visual binding costs, makes better control over feature bindings</li> <li>• Suggests a shared neural mechanism linking gamma activity and binding control</li> </ul>
<b>Research Question/Problem/Need</b>	Does experimentally increasing gamma-band neural synchronization causally influence feature binding performance and intelligence-related measures?

Important Figures

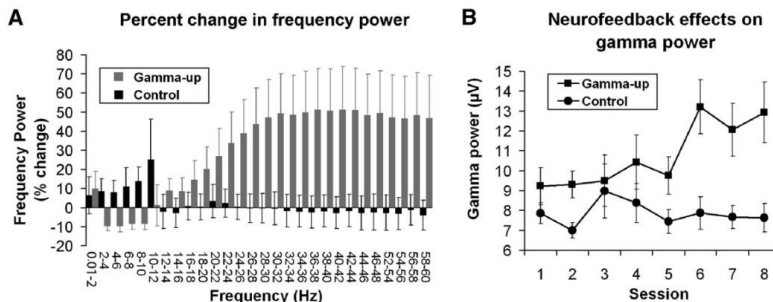

Fig. 2. The effects of neurofeedback on the power in frequency bands in the Gamma-up group and the Control group. The graph indicates the percent change in power between 0.01 and 60 Hz, divided in bins of 2 Hz (A). The increase of gamma band power (30–60 Hz) over the course of 8 neurofeedback sessions (B). Error bars depict standard error of the mean.

Binding costs

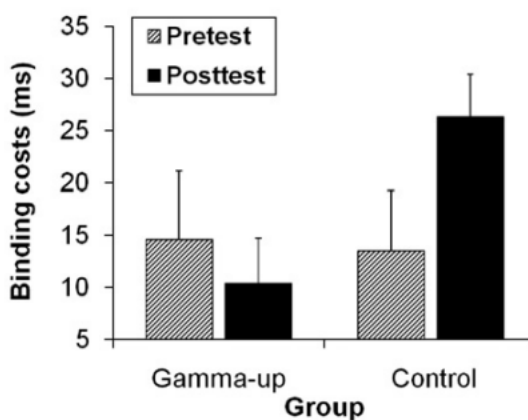

Fig. 3. The neurofeedback training resulted in a decrease of binding costs in the Gamma-up group and an increase of binding costs in the Control group (for the first half of the trials). Error bars depict standard error of the mean.

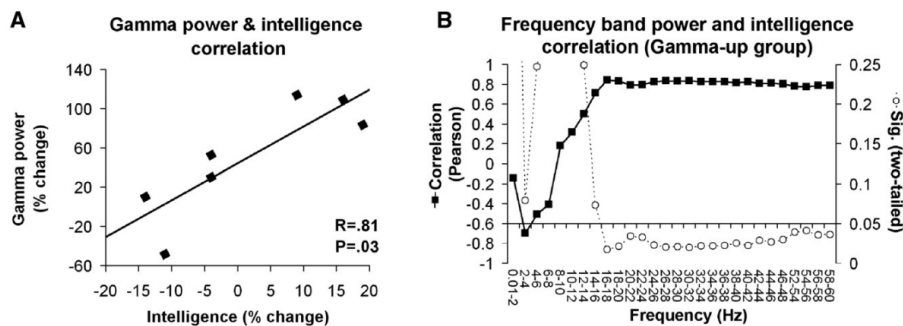

Fig. 4. There was a significant positive correlation between the percent change in gamma power (30–60 Hz) and the percent change in intelligence for the Gamma-up group (A). Figure 4B shows the correlation between the percent change in power between 0.01 and 60 Hz, divided in bins of 2 Hz with the percent change in intelligence. This graph shows that the positive correlation was present between 16 and 60 Hz, thus including both the gamma band (30–60 Hz) and the high-beta band (16–20 Hz). Error bars depict standard error of the mean.

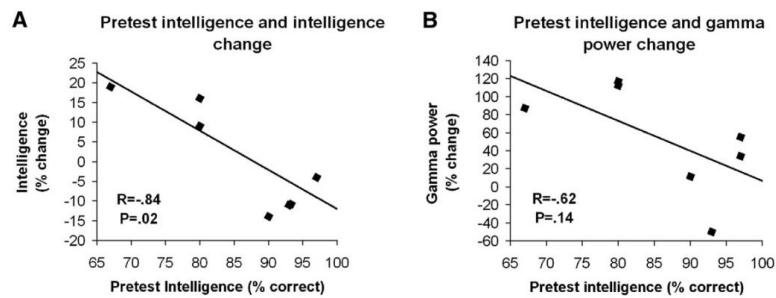

Fig. 5. Pretest intelligence correlated negatively with percent change of intelligence (A). There was no significant correlation between pretest intelligence and percent change in gamma power (B). These correlations suggest that pre-existing differences in learning ability did not underlie the positive correlation between percent change in intelligence and the percent change in gamma power.

### VOCAB: (w/definition)

- Feature binding: process where the brain integrates separate features into a coherent concept
- Binding costs: performance impairments that occur when previously bound features are partially repeated
- Event file: temporary cognitive representation that integrates stimulus features and responses
- Fluid intelligence: ability to reason and solve novel problems independent of learned knowledge
- ANCOVA: statistical method controlling for baseline differences while comparing group effects

### Cited references to follow up on

### Follow up Questions

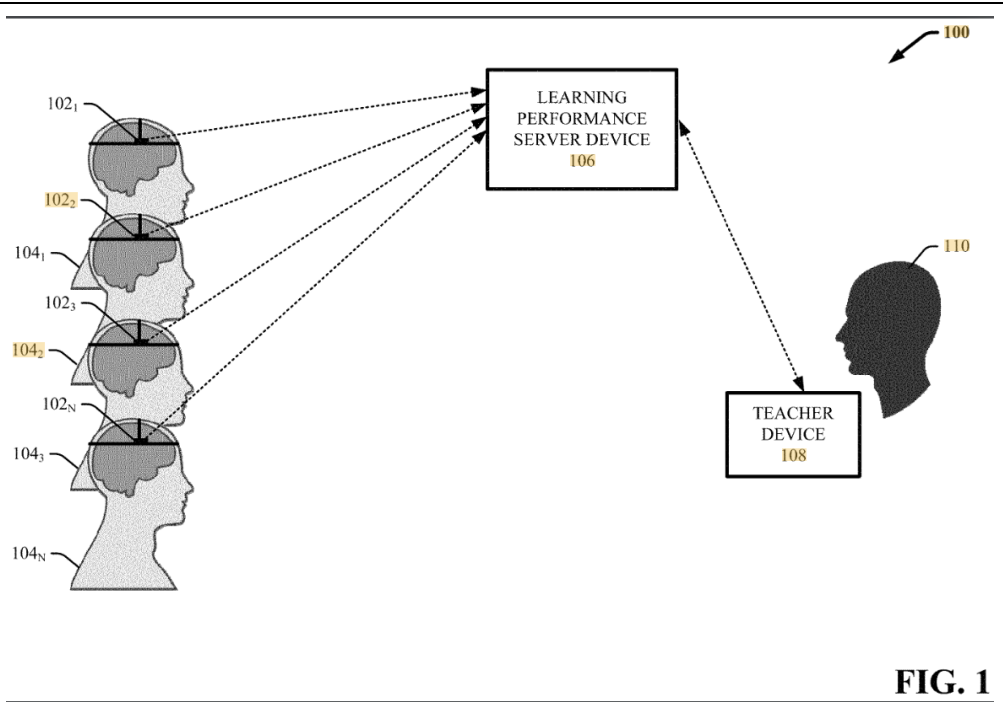

- Can **gamma neurofeedback effects** be replicated with **larger and more diverse samples**?
- Would targeting **other brain regions** (e.g., frontal cortex) strengthen intelligence effects?
- How long do the observed **binding and intelligence improvements** persist?
- Can beta-band neurofeedback selectively improve **visuomotor binding**, as theorized?
- Could gamma neurofeedback be applied to **clinical populations** with binding or executive-control deficits?

## Patent #1 Notes: Monitoring learning performance using neurofeedback

<b>Source Title</b>	Monitoring learning performance using neurofeedback
<b>Source citation (APA Format)</b>	Carr, K. G., & Das, P. (2020). <i>Monitoring learning performance using neurofeedback</i> (United States Patent No. US10839712B2). <a href="https://patents.google.com/patent/US10839712B2/en">https://patents.google.com/patent/US10839712B2/en</a>

<b>Source type</b>	Patent
<b>Keywords</b>	N/A
<b>#Tags</b>	
<b>Summary of key points + notes (include methodology)</b>	<ul style="list-style-type: none"> <li>• Patent describes a system and method to monitor a user's learning performance using NF data from a learning experience</li> <li>• Uses neuroimaging measurements (like EEG) to infer cognitive state and evaluate learning performance in real time.</li> <li>• A feedback component receives continuous neural measurements while a learner is engaged in a task</li> <li>• The system can be implemented as wearable hardware (headset, band) that streams EEG/NIRS data to a server for processing and evaluation.</li> <li>• Video or audio recordings of the learning situation can be correlated optionally with the neurofeedback data to identify specific content or moments where the learner struggled.</li> </ul>
<b>Research Question/Problem/ Need</b>	There is a need for real-time monitoring tools that can detect cognitive performance issues (attention lapses, poor working memory engagement) while learning is happening, not after.

Important Figures

<p><b>VOCAB: (w/definition)</b></p>	<ul style="list-style-type: none"> <li>• Near-infrared spectroscopy (NIRS): non-invasive method that measures changes in brain blood oxygenation related to neural activity</li> <li>• Learning performance information: Quantitative evaluation of a learner’s cognitive function derived from NF signals</li> <li>• Notification component: module that issues alerts when learning performance is below a specific level, allows for intervention</li> <li>• Cognitive function areas: defined mental processes like attention, mental effort, or working memory</li> </ul>
<p><b>Cited references to follow up on</b></p>	<ul style="list-style-type: none"> <li>• Near-Infrared Spectroscopy (NIRS) in cognitive monitoring: <a href="https://doi.org/10.1016/j.neuroimage.2011.05.028">https://doi.org/10.1016/j.neuroimage.2011.05.028</a></li> <li>• EEG in neurofeedback and cognitive load: <a href="https://doi.org/10.1016/j.neuropsychologia.2008.06.023">https://doi.org/10.1016/j.neuropsychologia.2008.06.023</a></li> <li>• Real-time brain state monitoring for adaptive learning: <a href="https://doi.org/10.1109/TBME.2015.2468615">https://doi.org/10.1109/TBME.2015.2468615</a></li> <li>• Machine learning classification of cognitive states from EEG: <a href="https://doi.org/10.3389/fnins.2018.00244">https://doi.org/10.3389/fnins.2018.00244</a></li> </ul>
<p><b>Follow up Questions</b></p>	<ul style="list-style-type: none"> <li>• Can real-time EEG markers used in this patent be applied to <b>predict neurofeedback training success</b> as in your project?</li> <li>• What specific EEG features (e.g., alpha, beta, gamma power) would best correlate with in-session learning performance as defined here?</li> <li>• How might the <b>notification components</b> be adapted to give actionable feedback in a cognitive training context rather than a classroom context?</li> <li>• Could machine learning improve the assessment component to predict <b>future performance or protocol adjustments</b>?</li> </ul>

- How does combining NIRS with EEG improve cognitive state detection compared to EEG alone?

## Patent #2 Notes: Multiple frequency neurofeedback brain wave training techniques, systems, and methods

<b>Source Title</b>	Multiple frequency neurofeedback brain wave training techniques, systems, and methods
<b>Source citation (APA Format)</b>	Keane, C. (2025). <i>Multiple frequency neurofeedback brain wave training techniques, systems, and methods</i> (United States Patent No. US12232882B2). <a href="https://patents.google.com/patent/US12232882B2/en">https://patents.google.com/patent/US12232882B2/en</a>
<b>Original URL</b>	<a href="https://patents.google.com/patent/US12232882B2/en">https://patents.google.com/patent/US12232882B2/en</a>
<b>Source type</b>	Patent
<b>Keywords</b>	N/A
<b>#Tags</b>	
<b>Summary of key points + notes (include methodology)</b>	<ul style="list-style-type: none"> <li>• Describes a Brain Training Feedback System (BTFS) that allows participants to learn how to increase, suppress, or inhibit specific brain-wave activity using NF.</li> <li>• BTFS uses both EEG signal obtaining and classification components and feedback generators that present real-time feedback based on processed neural data.</li> <li>• Innovates the ability to train multiple brain-wave modalities at the same time, rather than just one frequency band at a time.</li> <li>• System can use standard signal processing (like FFT) or AI-assisted machine learning engines (like LSTM neural networks) to deconstruct, classify, and model EEG signals for better real-time performance and customized feedback.</li> <li>• System can also include adaptive triggers that detect when a user is about to lose focus or shift state, which automatically generates interventions (ex. Sound bursts, flashes, or electromagnetic stimulation) to maintain desired brain states</li> </ul>
<b>Research Question/Problem/ Need</b>	Traditional neurofeedback systems are generally limited to training one brain-wave modality at a time and often rely on simple feedback signals, which may result in slower learning and reduced effectiveness.

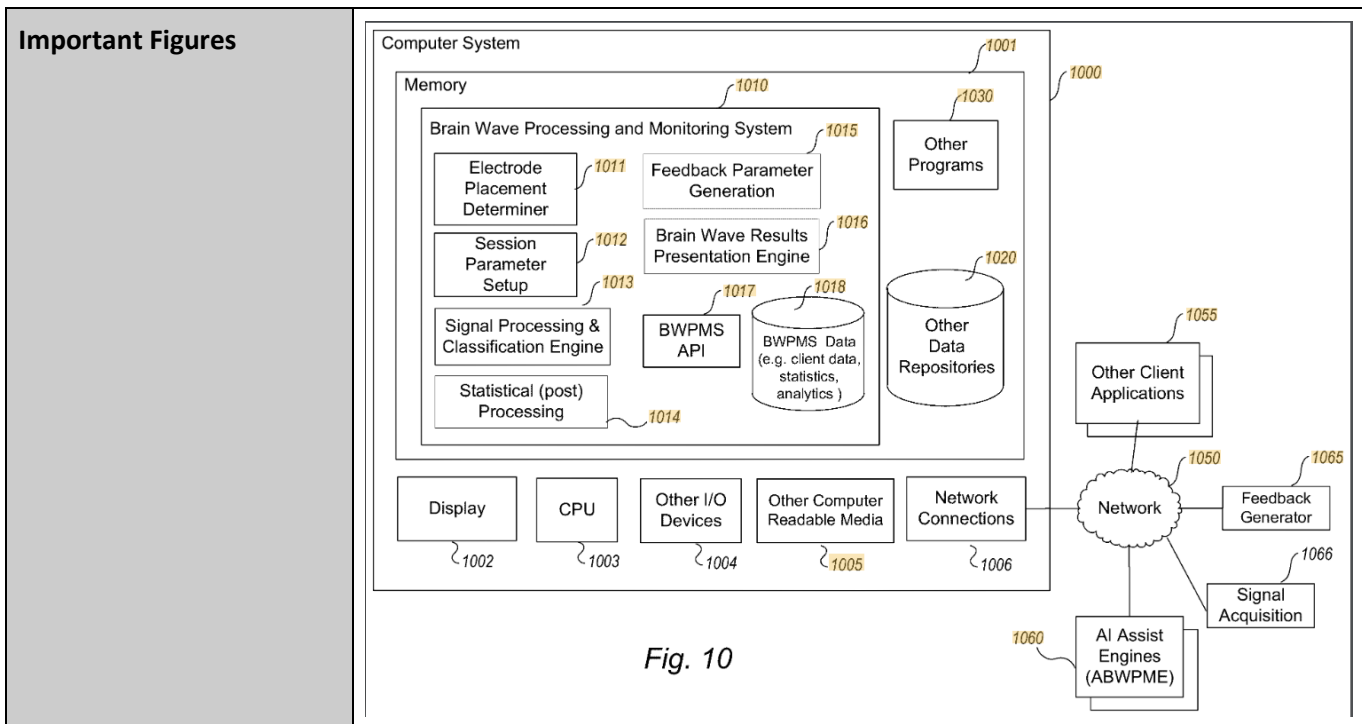

Fig. 10

<p><b>Important Figures</b></p>	
<p><b>VOCAB: (w/definition)</b></p>	<ul style="list-style-type: none"> <li>• Fast Fourier Transform (FFT): mathematical technique to convert time-based signals into frequency components for analysis</li> <li>• Long Short-Term Memory (LSTM): type of recurrent neural network used for temporal pattern learning, used in this system to model EEG dynamics</li> <li>• Moving average: statistical trend indicator calculated over multiple samples to detect the direction of patterns in EEG signals</li> <li>• Adaptive Feedback Generation: dynamic adjustment of feedback modalities based on real-time EEG analysis and ML predictions</li> </ul>
<p><b>Cited references to follow up on</b></p>	<ul style="list-style-type: none"> <li>• Machine learning for EEG signal classification: <a href="https://doi.org/10.3389/fnins.2018.00244">https://doi.org/10.3389/fnins.2018.00244</a></li> <li>• LSTM neural networks in brain signal processing: <a href="https://doi.org/10.1016/j.patcog.2018.05.009">https://doi.org/10.1016/j.patcog.2018.05.009</a></li> <li>• Real-time adaptive neurofeedback systems: <a href="https://doi.org/10.1109/TBME.2015.2468615">https://doi.org/10.1109/TBME.2015.2468615</a></li> <li>• EEG based feature extraction and classification: <a href="https://doi.org/10.1016/j.neuroimage.2010.03.022">https://doi.org/10.1016/j.neuroimage.2010.03.022</a></li> <li>• Quantitative EEG and neural modulation techniques: <a href="https://doi.org/10.1016/j.clinph.2009.07.034">https://doi.org/10.1016/j.clinph.2009.07.034</a></li> </ul>
<p><b>Follow up Questions</b></p>	<ul style="list-style-type: none"> <li>• How does simultaneous multi-frequency training influence learning outcomes compared to single-frequency training in cognitive performance?</li> <li>• How does the use of machine learning models (e.g., LSTMs) compare to FFT-only systems in terms of predictive accuracy and responsiveness?</li> <li>• Can the AI-assisted adaptive feedback mechanism be used to predict individual trainability early in sessions?</li> </ul>
