

Project Notes:

Project Title: How Synaptic Pruning Mediates the Relationship Between Gut Bacteria and ASD/ADHD

Name: Yerin Kim

Note Well: There are NO SHORT-cuts to reading journal articles and taking notes from them. Comprehension is paramount. You will most likely need to read it several times, so set aside enough time in your schedule.

| Keywords | gut microbiome psychology |
| #Tags | #psychology #gutmicrobiome #braindevelopment |
| Summary of key points + notes (include methodology) | Scientists have known for a while that the gut and brain are interconnected through the gut brain axis. Though there has been limited knowledge about how they work together, a recent study found that zebrafish that were exposed to healthy gut microbes only a week after birth were late to start joining shoals of fish compared to the other zebrafish who were exposed right at birth. This lack of sociability was also seen through the way their paths in the tank were more random and solitary compared to the zebrafish with normal gut microbiomes that generally swam closer to the transparent divider in the tank so they could be closer to the fish on the other side. These changes could also be seen physically in the brain: the fish that did not have a gut microbiome during early development were more packed with connections between neurons in the forebrain that affect social behavior, and less microglia, which are responsible for getting rid of waste in the brain and pruning unnecessary synapses. Even though it is still unclear how gut microbiota communicate with and create changes in the brain, and if the effect pertains to humans as well, this study still clearly shows that there is definitely a relationship between the two, and it would be interesting to further the studies on how the two communicate with each other, and the specific effects caused by specific bacteria. If this can be identified, it may open up new pathways to treatment for neurological/mental disorders. |
| Research Question/Problem/Need | How does delayed development of the gut microbiome affect the social psychology of zebrafish? |

| | |
|--|--|
| <p>Important Figures</p> |  <p>This visual shows how zebrafish with a normal microbiome primarily swam around the transparent divider near the fish on the other side, while the zebrafish without a gut microbiome had much more sporadic swimming pathways.</p> |

Article #2 Notes: Spreading the Word on a Possible Alzheimer's Treatment*

| | |
|--|---|
| Source Title | Spreading the Word on a Possible Alzheimer's Treatment |
| Source citation (APA Format) | Fields, R. D. (2020, May 27). <i>Spreading the Word on a Possible Alzheimer's Treatment</i> . <i>Quanta Magazine</i> . https://www.quantamagazine.org/spreading-the-word-on-a-possible-alzheimers-treatment-20200527/ |
| Original URL | https://www.quantamagazine.org/spreading-the-word-on-a-possible-alzheimers-treatment-20200527/ |
| Source type | Scientific magazine |
| Keywords | Alzheimer's, brain waves, microglia |
| #Tags | #microglia #brainwaves #exploration |
| Summary of key points + notes (include methodology) | Alzheimer's was previously discovered to cause weaker and more infrequent 40-hertz brain waves than in people without Alzheimer's. Using this information, neuroscientist Li-Huei Tsai and her lab used optogenetic stimulation on mice which shoots lasers directly into the neurons and made them fire 40 Hz impulses. This led to a decrease in amyloid plaques, an identifier for Alzheimer's. However, they recognized that this was not a realistic treatment option for humans, so instead, they used a different method to increase the power of gamma waves. When they used visual stimulation of a strobe of flashing lights, not only did the 40 Hz waves intensify, but the amyloid plaques were also removed. To find out what the direct cause of this was, they moved their focus to microglia which were discovered by Alois Alzheimer himself to be often found near amyloid plaques, and additional research confirmed that they got rid of the plaques. Microglia can sense electrical activity in the brain and are prompted to fix the wiring when waves become irregular. Furthermore, extending the period of the visual stimulation prevented neurons and synapses from disappearing. Sound stimulation had similar results in the auditory cortex, and in the hippocampus, the subject mice had increased memory. To understand more of the biological reasoning of how the brain waves cause microglia to remove plaques and protect neurons, further research by a team at Georgia Institute of Technology found that gamma visual stimulation caused microglia to produce more cytokines, which regulate neuroinflammation. The article concluded by hinting at the possibility of other types or ranges of light |

| | |
|---|--|
| | and sound simulations to treat different neurological diseases. |
| Research Question/Problem/Need | How can specific brain wave frequencies be used to treat Alzheimer's and what is the specific process that leads to the improvement? |
| Important Figures | N/A |
| VOCAB: (w/definition) | <u>Oscillate</u> : change in size or position around a central point <u>Optogenetic</u> : technology that allows fast and specific control of precise events in biological systems |
| Cited references to follow up on | Study in mice showing decreased amyloid plaques after firing 40 Hz waves: https://www.nature.com/articles/nature20587 Study in humans showing strobe lights increase brain waves and decrease AP: https://www.cell.com/neuron/fulltext/S0896-6273(19)30346-0?returnURL=https%3A%2F%2Flinkinghub.elsevier.com%2Fretrieve%2Fpii%2FS0896627319303460%3Fshowall%3Dtrue |
| Follow up Questions | What are the drawbacks and/or negative symptoms of using strobe lights to increase brain waves at a certain frequency? What are other methods that have been known to decrease amyloid plaques and how does this method compare? How can other methods be used to increase microglia production of cytokines without affecting brain waves? |

Article #3 Notes: Correlation between brain function and ADHD symptom changes in children with ADHD following a few-foods diet: an open-label intervention trial

Article notes should be on separate sheets

| | |
|--|---|
| Source Title | Correlation between brain function and ADHD symptom changes in children with ADHD following a few-foods diet: an open-label intervention trial |
| Source citation (APA Format) | Hontelez, S., Stobernack, T., Pelsser, L. M., van Baarlen, P., Frankena, K., Groefsema, M. M., Kleerebezem, M., Rodrigues Pereira, R., Postma, E. M., Smeets, P. A. M., Stopyra, M. A., Zwiers, M. P., & Aarts, E. (2021). Correlation between brain function and ADHD symptom changes in children with ADHD following a few-foods diet: An open-label intervention trial. <i>Scientific Reports</i> , 11(1), Article 1. https://doi.org/10.1038/s41598-021-01684-7 |
| Original URL | https://www.nature.com/articles/s41598-021-01684-7 |
| Source type | Scientific journal |
| Keywords | dietary intervention adhd brain activity |
| #Tags | #adhd #brainactivity #diet |
| Summary of key points + notes (include methodology) | (summary) Problem: Drugs for ADHD are not completely effective and have multiple side effects, so new treatment types should be considered. Goal: Since it is already known that ADHD negatively affects brain functioning, the study aimed to investigate the effect of the few foods diet on brain activation, especially in the indicated regions of interest. Method: To analyze differences in ADHD behavior, ADHD Rating Scale scores were compared at baseline and after the FFD, as well as inhibition task reaction times. Additional fMRIs were taken during the response inhibition tasks to see where brain activity increased. Findings: There was a significant decrease in ARS scores in 63% of the subjects, and a slight decrease in reaction time during the interference inhibition tasks (no real improvement in task performance/accuracy). There were no significant changes in |

the brain ROIs during the tasks; however, when activity throughout the whole brain was considered, both response inhibition type tasks caused an increase in activity in the precuneus (which also aligned with the ARS score changes). There were also significant decreases in ODD symptoms, which is often copresent with ADHD.

(key points)

- ADHD affects the following brain regions: frontal, parietal, temporal, occipital lobes and cerebellar and sub-cortical regions (activated during response inhibition).
- The few foods diet includes: rice, turkey, vegetables, pears, olive oil, ghee, salt, rice drink with added calcium and water
 - The extended FFD also includes: lamb, butter, small portions of wheat, corn, potatoes, some fruits, honey
- Precuneus plays a role in visuospatial processes, as well as brain’s default network (alert but not participation in task).
 - Depending on activity, may be over- or under-activated in people with adhd.

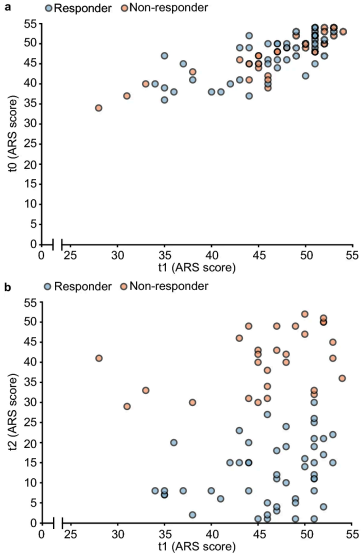

Research Question/Problem/Need

How effective is the few foods diet on ADHD, and how can its effect be explained through changes in brain activity?

Important Figures

| | N | Mean ARS score | | | | | | | | |
|------------------|----|----------------|------------|-------------|--------------|---------------------|----------------------|--------------|----------------------|----------------------|
| | | t0 (SD) | t1 (SD) | t2 (SD) | t1 versus t0 | | | t2 versus t1 | | |
| | | | | | Cohen's d | Difference (95% CI) | p value ^a | Cohen's d | Difference (95% CI) | p value ^a |
| FFD | 79 | 46.7 (5.1) | 46.2 (5.8) | 22.7 (15.6) | -0.08 | -0.5 (-1.3, 0.3) | 0.25 | -1.99 | -23.4 (-27.0, -19.9) | < 0.0001 |
| Stop-signal task | 53 | 46.7 (4.6) | 46.6 (5.4) | 21.5 (15.1) | -0.02 | -0.1 (-1.0, 0.9) | 0.87 | -2.21 | -25.1 (-29.4, -20.9) | < 0.0001 |
| Flanker task | 32 | 46.9 (4.4) | 46.9 (4.9) | 20.8 (16.1) | 0.00 | 0.03 (-1.4, 1.4) | 0.96 | -2.19 | -26.2 (-31.8, -20.5) | < 0.0001 |

This table shows how there was a significant decrease between t1 (baseline) and t2 (after FFD) ARS scores. The Cohen’s d further supports this as the negative value indicates how the mean of the t2 scores were quite less than the t1 mean score, and the p-value for t2 versus t1 also indicates that they are statistically significant.

| | |
|--|--|
| |  <p>This scatter plot further supports how there was a significant decrease in ARS scores before and after the FFD intervention. However, it also helps to point out the fact that a little less than half of the participants did not show a significant change in ARS scores/behavior after the FFD.</p> |
| <p>VOCAB: (w/definition)</p> | <p><u>Open-label</u>: both researchers and participants are aware of intervention</p> <p><u>Functional MRIs (fMRIs)</u>: as opposed to MRIs, fMRIs solely scan the brain, and they also detect metabolic activity over time using blood flow (blood oxygen levels).</p> <p><u>Inhibition</u>: forcefully restraining an instinctual response</p> <p><u>Mean beta weight (of brain)</u>: a combination of the different analyses in tiny 3D sections (voxels) of the brain to give an overall result.</p> <p><u>Covariate</u>: an additional (not primary) independent variable that may affect the outcome of the dependent variable</p> |
| <p>Cited references to follow up on</p> | <p>6 (“most stringent” FFD): https://journals.plos.org/plosone/article?id=10.1371/journal.pone.0169277</p> <p>9 (developing personalized diets for maximum ADHD effectiveness): https://adc.bmj.com/content/84/5/404</p> <p>26 (more info about precuneus?): https://www.sciencedirect.com/science/article/pii/S0924977X19304365?via%3Dihub</p> |
| <p>Follow up Questions</p> | <p>How does this study put the placebo effect into account?</p> <p>What is the role of the precuneus?</p> <p>What is the difference between researcher’s observation ratings and teacher ratings? Is the teacher referred to here just their primary school teacher?</p> <p>What do blood oxygen levels indicate in the brain?</p> <p>What is the difference between combined, inattentive, and hyperactive/impulsive ADHD?</p> <p>What is the main role of the precuneus?</p> <p>(implied through article) How would the results change if the subject were in a different age group (e.g. the elderly)?</p> |

(project-like) How can the fMRI scanning process be made more accurate and adaptable to movement and other technical issues?

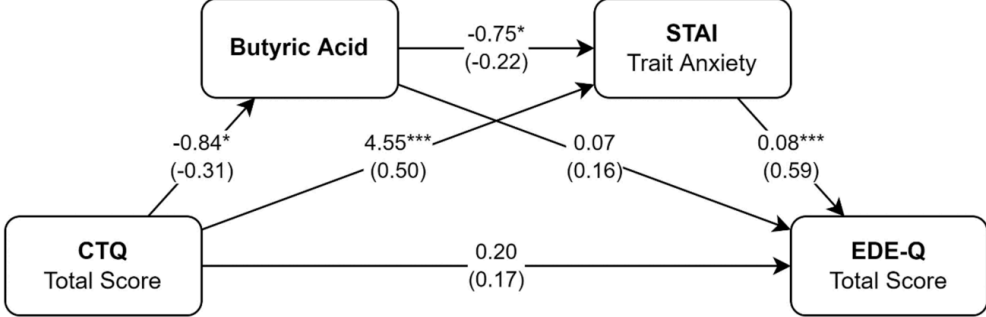

(project-like?) How do the compounds in specific foods lead to a change in brain functioning?

How were the FFD foods chosen? What was the criteria?

Article #4 Notes: Gut microbiota metabolites mediate the interplay between childhood maltreatment and psychopathology in patients with eating disorders

Article notes should be on separate sheets

| Source type | Scientific journal |
| Keywords | gut brain axis mental disorder |
| #Tags | #metabolites #mentalillness |
| Summary of key points + notes (include methodology) | <p>As cases of depression have been increasing during the pandemic, and uncertainty remains about the exact causes and the effectiveness of current treatments, this study sought out to discover which metabolites are positively (or negatively) linked to depression and what food sources they come from to provide insight on dietary recommendations for people with depression. To study this, they analyzed various databases which had information regarding metabolites and genomes in people with depression, food sources for those metabolites, the impact of antidepressant therapies, and the gut microbiota that were correlated with the specific microbiomes. They identified strong correlations between six metabolites and depression, among which one of them was vitamin A, which showed a positive correlation (higher levels of retinol and depression). They also found out that metabolites that were previously discovered to be linked with depression and were part of the amino-acid pathway (ex. Serotonin, leucine) were very likely to be expressed due to antidepressant medication.</p> |
| Research Question/Problem/ | What are the different metabolites that are linked to depression and what food |

| | |
|--|---|
| <p>Need</p> | <p>sources do they come from?</p> |
| <p>Important Figures</p> | <p>These were the metabolites that were tested, with the stars indicating the metabolites with high correlation.</p> |

| Source type | Journal article |
| Keywords | synaptic pruning microglia neurons astrocyte neural activity |
| #Tags | #backgroundinfo #synapticpruning #neurologicalprocesses |
| Summary of key points + notes (include methodology) | <p>(summary)</p> <p>This article explained the various processes that lead to synaptic pruning, mainly spontaneous vs. experience-driven neural activity induced pruning, immune-function induced pruning, and apoptosis, as well as the different cell types that performed the action (microglia, astrocytes, etc), and the different factors that may have triggered the action (neural activity, proteins, genes, environmental factors). Finally, they described how irregular patterns in synaptic pruning may be the cause of neurological disorders such as ASD and schizophrenia.</p> <p>(key points)</p> <ul style="list-style-type: none"> - Activity-induced pruning can happen at different stages of life based on what brain region it's taking place in, what subtype of neuron it is, and when it's taking place (which stage). - Spontaneous neural activity regulates S.P. during development of the cerebellum. - Cadherin-catenin complexes help stabilize synapses. (may be interesting if there are foods/bacterias that are known to increase amount of this) <ul style="list-style-type: none"> - NP1 and NP2 regulated synapse plasticity? - Microglial S.P. occurs in visual cortex, retinogeniculate system, auditory brainstem, auditory cortex, primary and secondary somatosensory |

cortices, and nucleus accumbens. (where to focus brain imaging?)

- Microglia do not only use phagocytosis to prune synapses, they also weaken climbing fiber synapses to increase chance of “winning” ones.
- Astrocytes also perform activity-induced synaptic pruning through phagocytosis.
 - There are more astrocytes, so they end up doing more pruning overall, but microglia are more specialized and faster at degradation.
- ASD brains have not enough S.P., schizophrenia has too much.
 - The genes related to pruning are C1QA, C3, and C3R.
 - Altered mRNA translation may cause autophagy which may be the cause of irregular S.P.
- Glial cells perform pruning of axons and sensory endings in Drosophila.

Research Question/Problem/Need
 What are the different processes that lead to synaptic pruning and how are they caused? What are the implications of irregular synaptic pruning (specifically in neurological disorders)?

VOCAB: (w/definition)
Spontaneous neural activity: Neural activity caused without a stimulus.
Experience-driven neural activity: Neural activity caused by an external

| | |
|---|--|
| | <p>factor/stimulus. <u>Cleave</u>: split or sever <u>Endogenous</u>: having an internal cause/origin <u>Synaptogenesis</u>: The process of forming and maintaining a synapse. <u>Autophagy</u>: The process of degrading proteins and organelles.</p> |

| Keywords | ADHD animal models rodents zebrafish fruit fly genetics epigenetics |
| #Tags | #modelorganism #adhd #behavioraltests |
| Summary of key points + notes (include methodology) | <p>(summary)</p> <p>Problem: The specific molecular explanation of psychological disorders, such as ADHD, are not well known due to their complex causes.</p> <p>Goal: The goal of this paper is to analyze various studies that used different types of model organisms to gain further information about the biology of ADHD, in particular, the genetics and epigenetics related to it.</p> <p>Method: Multiple behavioral tests, gene editing, and exposure to different toxins and drugs were performed on mus musculus, drosophila melanogaster, and danio rerio to identify ADHD behaviors and ADHD-related genes specific to each organism, as well as chemical or environmental factors that increased symptoms/likelihood of ADHD.</p> <p>Findings: Although there are most known symptoms and linked genes to mice models of ADHD, there are also many significant tests and genes known for ADHD models of danio rerio and drosophila. There are also studies that show a link between environmental factors and ADHD through epigenetics, but more research is required for direct causations.</p> <p>(key points)</p> |

- most of the genes that are correlated with ADHD are targeting genes involved in dopamine transmission (reward pathway), an important neurotransmitter in ADHD
- treatment for ADHD symptoms includes methylphenidate, amphetamine, and atomoxetine (maybe use to counter-check effects of experimental groups with the induced ADHD symptoms?)
- There are more strains that are known to cause hyperactivity compared to the other 2 ADHD symptom types as it is easier to identify hyperactivity (be aware of this 'bias' when looking at databases)
- ADHD and ASD are both early-onset neurodevelopmental disorders with high comorbidity and genetic overlap.
- ADHD can cause verbal and visuo-spatial working memory deficits
- Zebrafish are a common model organism for developmental biology due to their quick development and transparency as embryos.
 - Chemical compounds can also be exposed through immersion and not direct injection.
- Zebrafish larvae start moving consistently after 5 days, and adult movement pattern forms after ~1 month.
 - Video Tracking can be used to find specific measurements.
- HYPERACTIVITY IN ZEBRAFISH: "increase in distance swum, heightened acceleration during swim bouts"
 - also two choice serial reaction time task
- IMPULSIVITY IN ZEBRAFISH: The 5-CSRTT test can be performed on the zebrafish, which tests their patience of hitting LED lights for food as a measure of impulsivity.
- INATTENTION IN ZEBRAFISH:
 - Orientation - male zebrafish permitted to eavesdrop based on different stimuli?
 - Sustained attention - object recognition test, measuring time spent interacting with object on video screen
- Main ADHD candidate genes are adhesion G protein-coupled receptor L3.1 (lphn3.1/adgrl3.1) and period 1b (PER1B IS MORE WELL STUDIED) (ALSO IN TABLE BELOW)
 - both affect ADHD-like behavior through dopamine neurotransmission
- Zebrafish exposed to polychlorinated biphenyls (PCBs) or perfluorooctane sulphonate have been linked to increased ADHD (also in humans)
 - "decreased response to visual startle stimulus that could be a measure of attention"
- Too much acetaminophen use during pregnancy may increase likelihood of child showing ADHD symptoms
- JUST INTERESTING: Irregular circadian rhythms are often the cause of many psychiatric disorders, including ADHD
- HYPERACTIVITY IN FRUIT FLIES: data regarding locomotor activity (using Drosophila Activity Monitoring) and sleep help analyze this
 - Also grooming?
- INATTENTION IN FRUIT FLIES: vision-based behavioral paradigms

- IMPULSIVITY IN FRUIT FLIES: courtship disinhibition(?)
- Main ADHD candidate genes are SLC6A3 or DAT.
- HABITUATION is related to inattention in ADHD, as it is mainly caused by the inability to separate already known and new information
- Exposure to toxins such as BPA may contribute to ADHD
 - shown through fruit flies

Research Question/Problem/Need
 How can different model organisms be used to explain the underlying biological mechanisms that cause ADHD in current and future research endeavors?

Important Figures

| SUD | <i>Dat, Drd1, Drd2, Drd3</i> |

The leftmost list column shows genes that result in ADHD-like behaviors for each model organism. The second column shows comorbid (occurring together) disorders/symptoms. Finally, the third column shows additional genes/models that result in at least one of the three main ADHD symptom clusters, along with the ones that show additional comorbidities below.

Table 1
Summary of tests performed to study ADHD-related phenotypes and comorbid disorders in rodents, zebrafish and fruit flies.

| Disorder | Traits | Tests used | | |
|--------------------------|--|---|--|---|
| | | Rodents | Zebrafish | Fruit fly |
| ADHD-related phenotypes | Hyperactivity | Open-field test | Locomotive assays | Activity monitoring, capillary feeder (CAFE) assay, open-field assay |
| | Impulsivity | 5-choice serial reaction time task, Go/NoGo, continuous performance test, delay discounting, variable delay to signal | Locomotion (swimming) monitoring, 5-choice serial reaction time task | Courtship disinhibition assay |
| | Inattention | 5-choice serial reaction time task, continuous performance test, Go/NoGo, variable delay to signal | 5-choice serial reaction time task, object recognition task, social attention paradigm | Tethered flight paradigms, Buridan's paradigms, optomotor maze |
| Autism spectrum disorder | Impaired social behavior and communication, stereotypic behavior, cognitive rigidity | Three-chambered social approach, partition test, nesting behavior, ultrasonic vocalizations, open-field test, Morris water maze, T/Y maze | Shoaling assays, Y maze, interaction with conspecifics, visually-mediated social preference test | Habituation learning assay, grooming, social behavior assay, courtship song assay, Y-maze |
| Aggressive behavior | Aggression, social dominance | Resident intruder test, Dyadic social interaction test, social dominance test | Dyadic fight test, interaction with mirror image assay | Dyadic fight test |
| Anxiety | Anxiety-related behaviors, thigmotaxis | Open field, elevated plus maze, elevated zero maze, light dark box, stress-induced hyperthermia, Vogel test, defensive burying, four plate test | Active avoidance conditioning | Open-field assay |
| Major depression | Anhedonia, despair | Sucrose preference test, Porsolt forced swim test, Tail-suspension test, progressive ratio, female urine sniffing test | | Learned helplessness paradigm |
| Schizophrenia | Impaired sensorimotor gating | Prepulse inhibition test | Prepulse inhibition test | Larval prepulse inhibition test |
| Substance use disorders | Reward | Drug-induced locomotor activity or conditioned place preference | Place preference paradigm | Appetitive taste memory test, associative learning assay |

This table provides a clear overview of how the symptoms of the three different types of ADHD can be tested in each of the three model organisms, as well some other comorbid disorders.

VOCAB: (w/definition)

SNP: single nucleotide polymorphism (whole genetic sequence is same except for 1 base)

Etiology: The cause(s) of a disease or condition

Paradigm: A typical example or model

Motor impulsivity: (in zebrafish with ADHD) Sharp bouts of acceleration followed by periods of inactivity

Habituation: distinguishes information that is new vs already known

| Source type | Scientific article |
| Keywords | ADHD, Gut-Brain Axis, 16S rRNA sequencing, Microbiome, Biomarker |
| #Tags | Bacteria, ADHD, Procedure/Method |
| Summary of key points + notes (include methodology) | <p>(summary)</p> <p>Problem: ADHD is a common neurodevelopmental disorder that affects various aspects of life for a large number of people, but despite its commonality, the pathophysiology is not clearly known, specifically how it may be affected by diet.</p> <p>Goal: To determine if imbalanced gut microbiomes play a role in the biological causes correlated with ADHD.</p> <p>Method: Collect fecal samples from adolescent ADHD patients, analyze using 16S rRNA amplicon sequencing, and compare with clinical diagnoses and dietary patterns of ADHD.</p> <p>Findings: Although the actual amount of bacteria diversity between ADHD patients and healthy controls is not too varied (ADHD has higher diversity), ADHD patients have different abundances of some specific bacteria. A few types of bacteria were linked to differences in ADHD symptoms as well.</p> <p>(key points)</p> <ul style="list-style-type: none"> - At phylum level, ADHD group had higher relative abundance of <i>Fusobacteria</i>, <i>Actinobacteria</i>*, and <i>Proteobacteria</i>* (*non-significant) - At genus level, <i>Fusobacterium</i> had a greater relative abundance in ADHD group. - At species level, relative abundance of <i>Bacteroides uniformis</i>, <i>Bacteroides ovatus</i>, and <i>Sutterella stercoricanis</i> were higher in ADHD group than HC. |

- Also were correlated with ADHD symptoms and dietary patterns.
- *B. uniformis* and *B. ovatus* were also more abundant in ADHD patients in Aarts et al. study.
- It is possible that bacterial abundance in ADHD patients may be affected by different cultures, age groups, socio-environment status, etc.
- Also unclear if difference in bacterial diversity/abundance is a cause of ADHD, or if ADHD causes the changes.

Research Question/Problem/Need

How is bacteria in the gut microbiome correlated to the pathophysiology of ADHD?

Important Figures

(Fig 1a, b, c) Shannon index and Chao index both display diversity of bacteria, so a and b are expressing that there is a higher number of bacterial species in the group with ADHD. The Simpson index works oppositely number-wise, as 0 represents infinite diversity and 1 represents no diversity. So it follows the pattern that there is a greater abundance of bacterial species in ADHD.

| Genera | ADHD | Healthy controls | p value ^a |
|-----------------------|---------------------|---------------------|----------------------|
| Bacteroides | 59.78 (48.16–67.46) | 61.72 (50.91–66.43) | 0.717 |
| Prevotella | 0.02 (0.00–1.16) | 0.06 (0.01–7.11) | 0.116 |
| Parabacteroides | 3.83 (1.71–4.59) | 3.46 (1.77–6.73) | 0.865 |
| Phascolarctobacterium | 1.88 (0.32–3.98) | 1.82 (0.75–4.96) | 0.734 |
| Escherichia Shigella | 0.68 (0.11–5.24) | 1.82 (0.33–3.35) | 0.460 |
| Alistipes | 4.32 (0.02–7.37) | 0.68 (0.21–2.49) | 0.437 |
| Veillonella | 0.54 (0.06–2.04) | 0.39 (0.05–1.84) | 0.620 |
| Sutterella | 0.34 (0.01–2.42) | 0.28 (0.00–3.90) | 0.858 |
| Fusobacterium | 0.28 (0.02–3.28) | 0.02 (0.00–0.45) | 0.041* |
| Akkermansia | 0.01 (0.00–1.52) | 0.00 (0.00–0.34) | 0.304 |

(Table 3) This table shows the mean relative abundance of different bacterial genera in in ADHD group and HC (%). However, it should be noted that the only bacteria genus with a significant p-value is the *Fusobacterium*, which was shown to be much more abundant in people with ADHD.

VOCAB: (w/definition)

Pathophysiology: The study of how a disease or condition affects the patient both physically and biologically.
Phylogenetic: Study of evolutionary relationships between organisms
Alpha diversity: Abundance/variety of species within a community (local scale)
 - Beta diversity: ...comparative amongst different communities
OTU: A collection of 16S rRNA sequences that have a certain percentage of sequence divergence.
Phyla: Group/rank of classification between kingdom and class.
 - Genera: More specific rank of classification between family & species.

What is the randomized aspect of the ZFNs and how are they still able to bind to the target site?

How can ZFNs be harmful to organisms? What are the worst possible symptoms?

Patent #1 Notes: Method and system for diagnosis of neuropsychiatric disorders including attention deficit hyperactivity disorder (adhd), autism, and schizophrenia

| | |
|--|--|
| Source Title | Method and system for diagnosis of neuropsychiatric disorders including attention deficit hyperactivity disorder (adhd), autism, and schizophrenia |
| Source citation (APA Format) | Pettegrew, J., & Panchalingam, K. (2010, January 14). Method and system for diagnosis of neuropsychiatric disorders including attention deficit hyperactivity disorder (adhd), autism, and schizophrenia. |
| Original URL | https://patents.google.com/patent/US20100010336A1/en?q=(synaptic+pruning)&og=synaptic+pruning |
| Source type | Patent |
| Keywords | ADHD, autism, schizophrenia, neuropsychiatric disorders, biomarkers, neurodevelopment, magnetic resonance spectroscopy |
| #Tags | #neurodevelopmentalDisorderDetection #otherNeurologicalDisorders |
| Summary of key points + notes (include methodology) | <p>(summary)</p> <p>This invention describes a method and system for diagnosing and treating neuropsychiatric disorders using phosphorus magnetic resonance spectroscopic imaging (31P MRSI). The invention focuses on two main applications:</p> <p>Diagnosing Chronic Alcoholism: The method examines molecular alterations in the brain, including: Membrane phospholipid and high-energy phosphate metabolism, Synaptic transport vesicles, Phosphorylated proteins, Metabolites with N-acetyl moieties and gangliosides. These alterations are measured using 31P MRSI and compared between individuals with chronic alcoholism (both cognitively impaired and unimpaired) and healthy controls. The presence of specific molecular changes can be used to diagnose chronic alcoholism and potentially distinguish between cognitively impaired and unimpaired subgroups.</p> <p>Treating Depression: The invention proposes using acetyl-L-carnitine (ALCAR) to treat depression. Studies show that ALCAR treatment in depressed patients leads to: Normalization of PME(s-Tc) levels in the prefrontal region (brain area associated with mood regulation) and elevation of PCr levels in various brain regions. These changes are associated with clinical improvement in depression symptoms. ALCAR is proposed as a potential treatment for depression due to its effects on brain energy metabolism, membrane structure/function, and neurotrophic factors.</p> |

(key points)

The invention uses 31P MRSI to identify molecular changes in the brain associated with chronic alcoholism and depression. For chronic alcoholism, the invention offers a potential method for diagnosing the disorder and distinguishing between cognitively impaired and unimpaired subgroups. For depression, the invention proposes ALCAR as a treatment option based on its ability to normalize brain metabolite levels and improve symptoms.

Potential Benefits:

- Improved diagnosis and treatment of chronic alcoholism and depression.
- Development of new therapeutic strategies based on the identified molecular changes.
- Personalized medicine approaches based on individual brain chemistry.

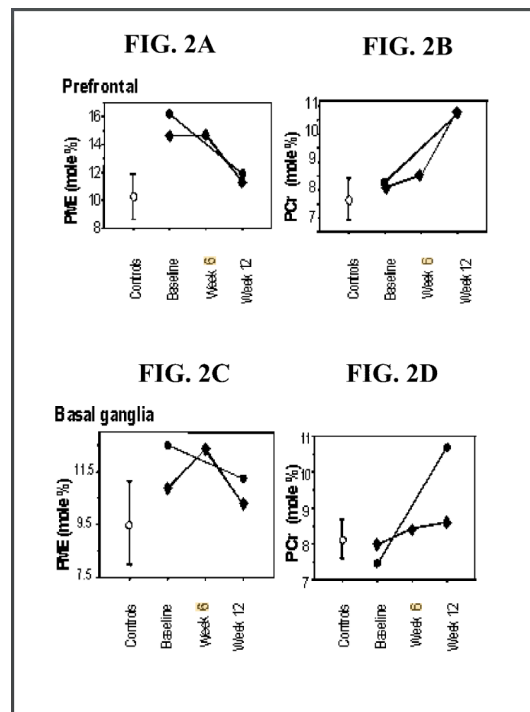

Future Directions:

Further research is needed to validate the diagnostic accuracy of the proposed method for chronic alcoholism. Clinical trials are necessary to confirm the efficacy and safety of ALCAR treatment for depression. Investigating the underlying mechanisms of action for both diagnostic and therapeutic applications would provide valuable insights for future development.

Research Question/Problem/Need

Can 31P MRSI detect brain chemistry changes to diagnose and treat chronic alcoholism and depression?

Important Figures

The figure includes four panels:

Fig. 2A: Shows the levels of PME in the prefrontal cortex, a brain region involved in mood regulation and executive function.

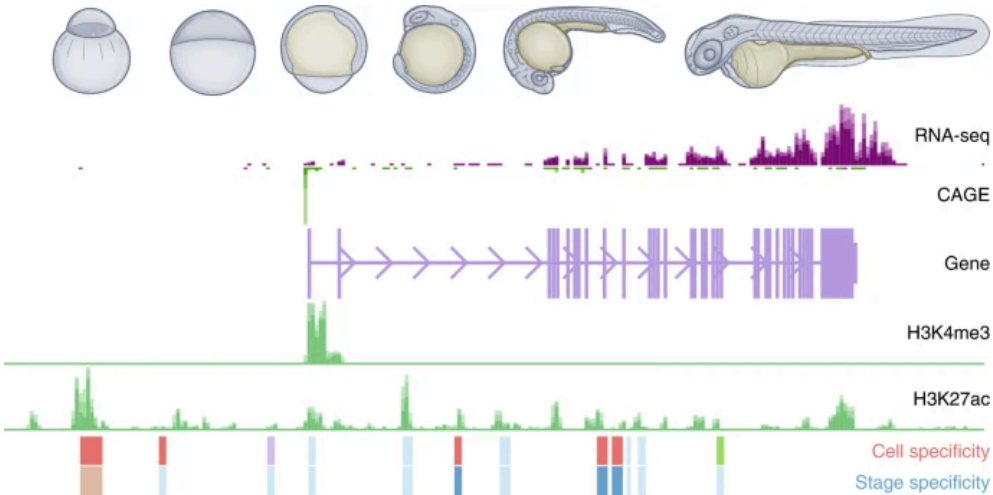

| | |
|---|--|
| | <p>Fig. 2B: Shows the levels of PME in the basal ganglia, a group of brain structures involved in movement and learning.</p> <p>Fig. 2C: Shows the levels of PCr in the prefrontal cortex.</p> <p>Fig. 2D: Shows the levels of PCr in the basal ganglia.</p> <p>Key findings:</p> <p>PME:</p> <p>In the prefrontal cortex (Fig. 2A), PME levels are higher in both CA-UI and CA-CI groups compared to controls. This suggests that chronic alcoholism, regardless of cognitive impairment, leads to changes in membrane phospholipid metabolism in the prefrontal cortex.</p> <p>In the basal ganglia (Fig. 2B), PME levels are lower in the CA-CI group compared to controls and CA-UI. This suggests that cognitive impairment in chronic alcoholism may be associated with specific changes in basal ganglia metabolism.</p> <p>PCr:</p> <p>In both the prefrontal cortex (Fig. 2C) and basal ganglia (Fig. 2D), PCr levels are lower in the depression group compared to controls. This suggests that depression is associated with decreased energy metabolism in these brain regions.</p> <p>Overall, the figure suggests that ³¹P MRSI can detect brain chemistry changes associated with chronic alcoholism and depression. These changes may have potential diagnostic and treatment implications.</p> |

| Research Question/Problem/Need | How does the gut microbiome affect neurological development in terms of the synaptic pruning process? |

Important Figures

This is Figure 1 of the paper. 1a shows the experimental timeline with the number of days after the mice were born when they were exposed to general bacteria, as well as the Bifidobacteria. 1b shows the bacterial abundance and diversity at different points after birth; the vast change between day 10 and day 20 could be due to difference in diet, as that period of time is when the pups have a significant increase in fiber intake from solid foods. 1c shows the different bacterial genera that dominate p4 and p10 conventionalized mouse gut; there is a significant decrease when compared with the p20 and dam microbiomes. 1d and 1e help support/refute previous claims made in the past (conventionalized mice have bacterial communities that mirror their donor microbiome profile, and microbiomes of male and female conventionalized mice are actually very similar contrary to previous studies).

Patent #2 Notes: Compositions and methods for treating disorders characterized by a defect in gpr56 expression or activity

| | |
|--|---|
| Source Title | Compositions and methods for treating disorders characterized by a defect in gpr56 expression or activity |
| Source citation (APA Format) | Piao, X. (2020, January 23). Compositions and methods for treating disorders characterized by a defect in gpr56 expression or activity. |
| Original URL | https://patents.google.com/patent/WO2020018913A1 |
| Source type | Patent |
| Keywords | GPR56, ASD (Autism spectrum disorder), synaptic pruning, Microglia, neurodevelopmental disorders, TG2 (Transglutaminase 2), RhoA signaling, mTOR signaling |
| #Tags | #proteinAffectingASD #treatmentPathway |
| Summary of key points + notes (include methodology) | <p>(summary) GPR56 is a protein involved in various biological processes, and its malfunction can contribute to several diseases, including metabolic disorders, inflammatory bowel disease, and cancer. Existing treatments for these conditions often have limitations, prompting the search for new therapeutic approaches.</p> <p>(key points) This patent proposes compositions and methods for treating disorders linked to GPR56 dysfunction. These include:</p> <ul style="list-style-type: none"> - GPR56 agonists: Molecules that activate GPR56, potentially mimicking its natural function and alleviating symptoms. - GPR56 positive allosteric modulators (PAMs): Substances that enhance the activity of GPR56 without directly binding to it, potentially offering a different approach to treatment. <p>The patent describes various ways to deliver the GPR56-targeting agents, such as oral, intravenous, or topical administration. The patent suggests that these compositions and methods could be used to treat a range of disorders:</p> <ul style="list-style-type: none"> - Metabolic disorders: Type 2 diabetes, obesity, non-alcoholic fatty liver disease. - Inflammatory bowel disease: Ulcerative colitis, Crohn's disease. - Cancer: Colon cancer, pancreatic cancer, breast cancer. - Other conditions: Bone diseases, neurodegenerative diseases. |

| | |
|---|--|
| | <p>Benefits: The proposed approach offers several potential advantages:</p> <ul style="list-style-type: none"> - GPR56 plays a crucial role in various diseases, making it a promising therapeutic target. The patent explores different compositions and methods, providing flexibility for tailoring treatment to specific needs. Compared to existing treatments, GPR56-targeting agents might offer better symptom control and fewer adverse effects. |
| Research Question/Problem/Need | Can GPR56 agonists or PAMs effectively treat disorders characterized by GPR56 dysfunction? |
| Important Figures | n/a |
| VOCAB: (w/definition) | <p><u>GPR56 (G protein-coupled receptor 56)</u>: The protein targeted by the compositions and methods described in the patent. It plays a role in various biological processes and its malfunction is linked to several diseases.</p> <p><u>Agonist</u>: A molecule that activates a receptor, in this case GPR56. GPR56 agonists mimic the natural ligand (activating molecule) of GPR56, potentially triggering its desired function.</p> <p><u>Positive allosteric modulator (PAM)</u>: A substance that enhances the activity of a receptor without directly binding to it. In this case, GPR56 PAMs would increase the response of GPR56 to its natural ligand, even at low concentrations.</p> |

Patent #3 Notes: Beta-2 chimaerin as a mediator of axonal and synaptic pruning

| | |
|--|--|
| Source Title | Beta-2 chimaerin as a mediator of axonal and synaptic pruning |
| Source citation (APA Format) | Kolodkin, A., Kazanietz, M., & Riccomagno, M. (2013, December 19). Beta-2 chimaerin as a mediator of axonal and synaptic pruning. |
| Original URL | https://patents.google.com/patent/WO2013188666A1 |
| Source type | Patent |
| Keywords | Beta-2 chimaerin, Axonal pruning, Synaptic elimination, Neurological diseases, Beta-Chimaerin modulators, Rac GTPase, Neuropilin-2 |
| #Tags | #proteinAffectingSynapticPruning #regulatingNeurologicalFunctioning |
| Summary of key points + notes (include methodology) | <p>(summary) This patent describes the use of a protein called beta-2 chimaerin to promote the natural process of "axonal and synaptic pruning" in the brain. Pruning removes unnecessary connections between brain cells, which is important for healthy brain function.</p> <p>(key points) Beta-2 chimaerin is identified as a protein involved in pruning. The patent details its structure and function.</p> <p>Methods are provided for producing and purifying beta-2 chimaerin. This paves the way for its potential use in therapeutic applications.</p> <p>The patent suggests that beta-2 chimaerin could be used to treat or prevent neurological diseases. Examples include Alzheimer's, Parkinson's, and schizophrenia, where abnormal pruning is implicated.</p> <p>Potential benefits: Stimulating pruning could help clear away harmful protein aggregates associated with neurodegenerative diseases. Promoting healthy pruning patterns could improve cognitive function and memory.</p> <p>Limitations and unknowns: The patent focuses on the basic science of beta-2 chimaerin. More research is needed to understand its safety and effectiveness as a treatment. The exact role of beta-2 chimaerin in different brain diseases is still being</p> |

| | |
|---|---|
| | <p>investigated.</p> <p>Overall, this patent presents a promising avenue for developing new therapies for neurological diseases by targeting the natural process of brain cell pruning.</p> |
| Research Question/Problem/Need | Can beta-2 chimaerin, a regulator of brain cell pruning, be harnessed to treat neurological diseases linked to abnormal pruning patterns? |
| Important Figures | n/a |
| VOCAB: (w/definition) | <p><u>Recombinant cells</u>: Cells that have been engineered to express a specific protein, such as beta-2 chimaerin.</p> <p><u>Guanylate nucleotide exchange factor (GEF) activity</u>: The ability of beta-2 chimaerin to activate another protein involved in pruning.</p> <p><u>Catalytic domain</u>: The part of the protein that performs its enzymatic activity, potentially involved in cleaving proteins during pruning</p> |
